---

The present series, entitled "Smithsonian Miscellaneous Collections," is intended to embrace the principal publications issued directly by the Smithsonian Institution in octavo form; and is designed to contain reports on the present state of our knowledge of particular branches of science, instructions for collecting and digesting facts and materials for research, lists and synopses of species of the organic and inorganic world, reports of explorations, aids to bibliographical investigations, etc., generally prepared at the express request of the Institution.

The "Smithsonian Contributions to Knowledge," in quarto form, embraces the records of extended original investigations and researches, resulting in what are believed to be new truths, and constituting positive additions to the sum of human knowledge.

In both of these series each article bears a distinct number, and is also separately paged unless the entire volume relates to one subject. The date of the publication of each article is that given on its special title-page, and not that of the volume in which it is placed. In many cases papers have been published and largely distributed, several months before their combination into volumes.

## ADVERTISEMENT

The accompanying paper, by Dr. Guy Hinsdale, on "Atmospheric Air in Relation to Tuberculosis," is one of nearly a hundred essays entered in competition for a prize of \$1,500 offered by the Smithsonian Institution for the best treatise "On the Relation of Atmospheric Air to Tuberculosis," to be presented in connection with the International Congress on Tuberculosis held in Washington, September 21 to October 12, 1908. The essays were submitted to a Committee of Award, consisting of Dr. William H. Welch, of Johns Hopkins University, Chairman; Prof. William M. Davis, of Harvard University; Dr. George M. Sternberg, Surgeon-General, U. S. A., Ret'd; Dr. Simon Flexner, Director of Rockefeller Institute for Medical Research, New York; Dr. Hermann M. Biggs, of New York, General Medical Officer, Department of Health, New York City; Dr. George Dock, Medical Department, Washington University, St. Louis; and Dr. John S. Fulton, of Baltimore, Secretary General of the Congress on Tuberculosis. Upon the recommendation of the committee, the prize was divided equally between Dr. Guy Hinsdale, of Hot Springs, Virginia, and Dr. S. Adolphus Knopf, of New York City.

At the request of the Institution, Dr. Hinsdale has revised his essay so as to indicate some of the advances made in the study of the subject during the past five years.

CHARLES D. WALCOTT,  
*Secretary of the Smithsonian Institution.*

WASHINGTON, DECEMBER, 1913.

TERMS OF COMPETITION  
SMITHSONIAN INSTITUTION

HODGKINS FUND PRIZE

In October, 1891, Thomas George Hodgkins, Esquire, of Setauket, New York, made a donation to the Smithsonian Institution, the income from a part of which was to be devoted to "the increase and diffusion of more exact knowledge in regard to the nature and properties of atmospheric air in connection with the welfare of man." In furtherance of the donor's wishes, the Smithsonian Institution has from time to time offered prizes, awarded medals, made grants for investigations, and issued publications.

In connection with the approaching International Congress on Tuberculosis, which will be held in Washington, September 21 to October 12, 1908, a prize of \$1,500 is offered for the best treatise "On the Relation of Atmospheric Air to Tuberculosis." Memoirs having relation to the cause, spread, prevention, or cure of tuberculosis are included within the general terms of the subject.

Any memoir read before the International Congress on Tuberculosis, or sent to the Smithsonian Institution or to the Secretary-General of the Congress before its close, namely, October 12, 1908, will be considered in the competition.

The memoirs may be written in English, French, German, Spanish or Italian. They should be submitted either in manuscript or type-written copy, or if in type, printed as manuscript. If written in German, they should be in Latin script. They will be examined and the prize awarded by a Committee appointed by the Secretary of the Smithsonian Institution in conjunction with the officers of the International Congress on Tuberculosis.

Such memoirs must not have been published prior to the Congress. The Smithsonian Institution reserves the right to publish the treatise to which the prize is awarded.

No condition as to the length of the treatises is established, it being expected that the practical results of important investigations will be set forth as convincingly and tersely as the subject will permit.

The right is reserved to award no prize if in the judgment of the Committee no contribution is offered of sufficient merit to warrant such action.

CHARLES D. WALCOTT,  
*Secretary of the Smithsonian Institution.*

WASHINGTON, D. C., FEBRUARY 3, 1908.

## PREFACE

The rapid progress in the antituberculosis movement throughout the world in the last five years has made it necessary to make some changes in the present essay as originally presented to the Smithsonian Institution in 1908. Much that then seemed novel appears almost commonplace now. An extraordinary amount of research has been carried out with reference to the atmospheric air during these later years. The whole theory of ventilation has been stated in new terms; the presence of ozone in the atmosphere, a subject that has always appealed to the popular fancy since its discovery, has been restudied and its physiologic action assigned a value different from that commonly ascribed to it; the properties of strong sunlight and Alpine air have been marshalled for the combat with surgical tuberculosis, particularly in children.

Physiologists in Europe and America have lately made most interesting studies of the blood at the higher altitudes and their observations are constantly throwing new light on the entire subject of aerotherapy, replacing old impressions and beliefs with a scientific basis on which we may confidently build.

There never was a time when the outdoor life and the accessories for the atmospheric treatment of all tuberculous persons were so well systematized and placed in harmony with the other hygienic measures adopted for their cure.

What the result has been we have endeavored to show and what the future holds for us we are eagerly awaiting.

May the Smithsonian Institution, through its Hodgkins Fund, continue to stimulate inquiry and disseminate the fruits of the worldwide efforts to the better understanding of the great problems that yet remain unsolved.

GUY HINSDALE.

### ATMOSPHERIC AIR IN RELATION TO TUBERCULOSIS

BY GUY HINSDALE, A. M., M. D., HOT SPRINGS, VA.

(WITH 93 PLATES)

#### CHAPTER I. INTRODUCTION

We are compelled to acknowledge at the outset the difficulty or impossibility of analyzing the relationship of atmospheric air to tuberculosis so as to isolate the influence of all other factors. It would be totally useless and impossible to consider air independent of sunlight, heat, rainfall, the configuration of the earth's surface; racial characteristics, social environment, including dwellings, clothing, food, and drink.

As a resultant of all these and many other factors in the tuberculosis problem, we obtain the figures of mortality which are published from time to time by various cities, states, and nations. The problem seems incapable of solution. One might as well survey an oak that has grown for centuries and set out to determine the relative value of the atmospheric air, the sunlight, the rainfall, and the various constituents of the soil and its environment in producing the sturdy, deeply rooted, and wide-spreading tree which has seen ages come and go.

The world-wide efforts now made to determine the nature of this infection and especially its bacteriologic and pathologic character are accompanied by a general effort to limit its spread. We are encouraged to believe that future generations will be provided with a practical and efficient method of destroying this insatiate monster.

Undoubtedly we have begun at the right end, but we only began within the memory of nearly all of us, only thirty-two years ago, when the true cause of the disease was first isolated and revealed to the human eye.

Previously we were as the blind leading the blind, groping about in search of special climates, special foods or medicines, meeting with more or less success in so far as the dietetic, hygienic, out-of-door plan of treatment was carried out. These curative measures succeeded then, as they succeed now, but preventive measures

worthy the name were entirely unknown. The enemy once revealed in its hiding place, and various facts in its life history determined, the logical result was a gradual—very gradual—dawn which promised better things. Now the world has seen a great light and we wonder how intelligent men could have dwelt in those caverns of ignorance and even refused to come out for years while the men in the laboratory beckoned with signs which then seemed so uncertain but now so clear. As late as 1890 the medical mind did not grasp the necessity for preventive measures. As one asleep it heard voices but was slow to waken; it starts and rubs its eyes and looks about, waiting for some word or message that will bring it to its senses.

It was in 1891 that the first society for the prevention of tuberculosis was organized. This was started in France by M. Armaingaud, of Bordeaux. The second was the Pennsylvania Society for the Prevention of Tuberculosis organized in Philadelphia in 1892. These were the pioneers in Europe and America. They devoted their energies to a campaign with three cardinal features: (1) the education of the public in reference to the nature of the disease and its means of prevention; (2) the passage of suitable laws regarding notification, the restriction of expectoration, disinfection, etc.; and (3) the care of consumptives and the establishment of sanatoria by public or private means in suitable localities.

The wonderful growth of this movement for preventive measures is now seen in the establishment of 1,228 societies for the prevention of tuberculosis in America alone, and in the erection of 527 sanatoria in this country (1913).<sup>1</sup> The State of Pennsylvania alone has appropriated in one Act of Legislature \$2,000,000 for this purpose and one citizen of the state, Mr. Henry Phipps, has given an equal amount for the scientific study as well as the practical treatment of this disease in all its bearings.<sup>2</sup>

<sup>1</sup> The State of New York leads all other states in the number of new organizations and institutions established during the last two years. The total number of beds for consumptives in the United States now exceeds 33,000.

<sup>2</sup> The Pennsylvania legislature appropriated \$1,000,000 in 1907, \$2,000,000 in 1909, \$2,624,808 in 1911, and \$2,659,660 in 1913 for tuberculosis work alone. This is under the direction of Dr. Samuel G. Dixon, the Commissioner of Health.

There are at the present time two State Sanatoria in Pennsylvania in operation.

*Mont Alto*, Franklin Co.

No. of patients under treatment..... 957

Elevation .....1,650 ft.

Note:- The figures in Franklin County include the deaths of the State Sanatorium.  
 The death rate for Franklin County exclusive of Mont Alto would be 100-149.

IN PENNSYLVANIA BY COUNTIES FOR THE YEAR 1912

The late Dr. Henry I. Rowditch, of Boston, was one of the first physicians in America to recognize the value of constant out-door life in the treatment of tuberculosis and was accustomed to send such patients on easy journeys by carriage so that they might have the benefit of as much out-door air as possible, becoming gradually inured to the elements.

The late Dr. Alfred L. Loomis, of New York, was one of the first to systematically send tuberculous patients to the Adirondack forest that they might have the benefit of the purest and most invigorating air obtainable and, like the physicians of ancient Rome who sent consumptive patients to the pine forests of Libya, he believed that the terebinthinate exhalations from the standing pines exerted a most beneficial influence on pulmonary affections. Dr. Loomis's results were so gratifying that he encouraged Dr. Edward L. Trudeau to care for such patients in the Adirondack Mountains throughout the year, and Dr. Trudeau, with his help, founded in 1884 the first sanatorium for tuberculosis in America.<sup>1</sup>

This Adirondack Cottage Sanitarium, now in its thirtieth year, has been the inspiration of sanatoria for tuberculosis throughout the country. Its success in restoring so many patients to health and usefulness is not wholly estimated in figures. It has established

---

*Cresson, Cambria Co.*

No. of patients under treatment..... 337  
 Elevation .....2,550 ft.

*Hamburg, Berks Co.*

In the course of construction and will be completed some  
 time in 1914.  
 Capacity ..... 480  
 Elevation ..... 550 ft.

These institutions care for both incipient and far advanced cases. The interior arrangement of the sanatoria at Cresson and Hamburg is such that they can be used for the different classes of cases as demand may necessitate. There is a waiting list of those desiring admission to these institutions at all times.

The State maintains 115 Tuberculosis Dispensaries, which are located throughout the 67 counties in the commonwealth. There are 220 physicians and 120 visiting nurses employed in these dispensaries.

By the courtesy of Dr. Samuel G. Dixon, Commissioner of Health, we are able to show in a map the distribution of tuberculosis in the counties of Pennsylvania (pl. I). This shows, as in an earlier map by the author, that the disease is least prevalent in the higher, forest covered regions of the State.

<sup>1</sup>A. L. Loomis, M. D. Evergreen Forests as a therapeutic agent in pulmonary phthisis (Trans. Amer. Climatological Ass., Vol. 4, 1887). See page 134.

a practical method of cure and has done much to correct the earlier unfounded and mischievous notions that prevailed as to what was necessary for the cure of tuberculosis.

Taking this institution as an example, let us see what bearing it may have on our general subject, the relation of the atmospheric air to tuberculosis:

(a) It is in the midst of an evergreen forest of over 10,000 square miles; (b) the atmosphere is pure, or at least as pure as may be obtained on the continent; (c) the air is moderately moist; (d) the rainfall averages 35 inches; (e) the air is moderately rarified, owing to (f) an elevation of 1,750 feet; (g) owing to its northern situation (latitude  $44^{\circ}$ ) and its elevation (1,750 feet) (h) the climate is cold in winter and (i) subject to rather sudden changes with an annual range of  $59^{\circ}$  C. or  $138^{\circ}$  F.

## CHAPTER II. VALUE OF FORESTS, MICRO-ORGANISMS, ATMOSPHERIC IMPURITIES.

### GENERAL BENEFIT OF FORESTS

It has come to be an axiom in phthisiology that the air of an evergreen forest is eminently suitable for a patient with tuberculosis.<sup>1</sup> As we have previously mentioned, the pine forests of Libya were used two thousand years ago for the cure of "ulcerated lungs." At that period the pines abounded and gave the locality a reputation as a health resort for affections of the lungs. But the ravages of time, aided by fire and sword, not to speak of domestic needs, have obliterated all vestiges of these ancient forests.

The successful institutions located in the Hartz Mountains, the Black Forest of Germany, in the Forest of Ardennes, the State Forest Reserve of Pennsylvania, and the Adirondaek Forest in New York owe much of their success to the abundant use of the purest air both day and night.

European Governments have long recognized the great value of

<sup>1</sup>The following quotation from Pliny shows that it was generally agreed in his day that the forests and especially those which abound in pitch and balsam are the most beneficial to consumptives or those who do not gather strength after long illness, and that they are of more value than the voyage to Egypt:

"Sylvas, eas duntaxat quae picis resinæque gratia redantur, utilissimas esse phthisicis, aut qui longa aegritudine non recolligant vires, satis constat; et illum coeli aera plus ita quam navigationem Aegyptian proficere, plus quam lactis herbidos per montium aestiva potus."—C. Plinii, Hist. Nat. lib. xxiv. Cap. 6.

Photograph Furnished by Dr. Albert Sander

their forests and have protected them by strictly enforcing intelligent laws so that they may be forever preserved and improved. The history of forestry in the United States and Canada has been that of ruthless, unrestrained, wholesale destruction of nearly all our standing pine, and heavier spruce. In recent years, however, we have seen the establishment of Government reserves, State reserves, and State laws for their protection; the organization of the American Forestry Association, the American Forest Congress, the Society for the Preservation of the Adirondack Forest; the Schools of Forestry at Yale, Harvard University and Mont Alto, Penna. All these remedial measures have come very late, but will undoubtedly exert a strong influence for good.<sup>1</sup>

Aside from the general beneficial influence of forests, universally recognized by climatologists, these natural parks have proved the means of restoring thousands of persons suffering from tuberculosis and diseases of the respiratory system.

#### QUALITIES OF FOREST AIR AND SOIL

The qualities of forest air and forest soil have been studied by E. Ebermayer<sup>2</sup> who shows that, like that of the sea and mountains, forest air is freer from injurious gases, dust particles, and bacteria. It was shown that the vegetable components of the forest soil contain less nutritive matter (albuminoid, potash, and phosphates and nitrates) for bacterial growth; that the temperature and moisture conditions are less favorable; that the sour humus of the forest soil is antagonistic to pathogenic bacteria; finally that, so far, no pathogenic microbes have ever been found in forest soil; hence this soil may be called hygienically pure.

The soil is protected from high winds by forest growth and undergrowth; the upper soil strata are slow to dry out and wind sweeping over them carries few micro-organisms into the air. As may be expected, fewer microbes are found in forest air than outside their limits. Serafini and Arata have proved this experimentally.<sup>3</sup> They

<sup>1</sup> The chief forester of the United States has in 1913 under his care in 160 forest reservations a total of 165,000,000 acres of forest land. The present Chief Forester has done excellent work in the prevention of serious forest fires.

<sup>2</sup> E. Ebermayer: (1) Hygienic significance of forest air and forest soil. (2) Experiments regarding the significance of humus as a soil constituent; and influence of forest, different soils, and soil-covers on composition of air in the soil. Wollny, 1890 (*Hygeia*, August 15, 1891).

<sup>3</sup> Serafini and Arata: *Intorno all'azione dei boschi sui mikro organismi trasportati dai venti.*

exposed plates in the forest air and on its outskirts and tabulated their countings of bacteria for forty successive days from May 6. They made three classes—molds, liquefying and non-liquefying bacteria. They found that, with one exception, one or two of these classes were always less numerous in the forest than on its outskirts and generally from twenty-three to twenty-eight times less. Serafini makes the point that bacteria coming from the outside are reduced in number by a sort of filtration process. Thus we see that the air of forests is comparatively free from endogenous and exogenous bacteria—none of them in any case being pathogenic.<sup>1</sup>

#### CARBON DIOXIDE IN FORESTS

Puchner shows that the air in the forest contains generally more carbonic acid gas than in the open, due to the decomposition of litter.<sup>2</sup> But this difference must be almost inappreciable. As we know, the law of diffusion of gases renders it impossible for variations in the relative proportion of the atmospheric constituents to be more than transitory. Diffusion is greatly favored by the winds which sweep through the tree tops, especially where they are not too crowded.

The fact that so many sanatoria for tuberculosis are located in or near forests makes it very important to dwell a little longer on the constituents of the air in these localities. We know that forests, as well as all other forms of vegetal growth, take up large quantities of carbonic acid, retaining the carbon and rejecting the oxygen, and the question naturally arises, does it sensibly change the relative quality of either constituent so that the composition of the air is slightly different in the woods? Prof. Mark W. Harrington, lately chief of the United States Weather Bureau, undertook to answer that question, both with reference to carbonic acid, oxygen, and ozone, with some interesting results.<sup>3</sup> Repeated observations show that each constituent is curiously uniform in quantity in the free air. It has been thought that carbonic acid is quite variable but the introduction of better methods of observation shows that, except in confined places where the gas is produced, the variations are very

small. A little study shows that the carbonic acid gas taken up by a forest is a very small quantity compared with that which passes the forest in the same time with the moving air. Grandeau<sup>1</sup> estimated the annual product of carbon by a forest of beeches, spruces, or pines as about 2,700 pounds per acre. This corresponds to 9,900 pounds of carbonic acid gas or 69,300 cubic feet. Now, if the average motion of the air is five miles an hour, a low estimate, and the layer of air from which the gas is taken be estimated at one hundred feet thick, there would pass over an acre 550 million cubic feet in one hour. This air must contain about three parts in ten thousand of carbonic acid gas and the total amount of the latter per hour is 165,000 cubic feet. But this is two and two-thirds, or more than twice as much as that taken up by the trees in the entire season, so that the air could provide in thirty minutes for the wants of the trees for the entire season. Prof. Harrington shows that the ratio of carbonic acid used to that furnished is only one part in 8,600.

#### OXYGEN IN FORESTS

Again, the additions of oxygen to the air would form a still smaller percentage of the oxygen already present, for this gas makes up 20.938 per cent of the air against a thirtieth of one per cent obtainable from this source.

#### OZONE IN FORESTS

The occurrence of ozone in the air of forests, especially coniferous forests, has been credited, since its discovery by Schoenbein in 1840, with affording remarkable health-giving qualities. This opinion has become firmly fixed in the minds of the public and, to a large extent, has been accepted by the medical profession as an evidence of high oxidizing power at once corrective of decaying vegetation and exhilarating and curative to mankind. Popular belief usually has some basis for its existence; indeed, meteorologists made regular estimations of ozone in the atmosphere by testing with sensitized papers and the results were published in connection with statistics of health resorts.<sup>2</sup>

The Schonbein test is based on the power of ozone to free iodine from a solution of potassium iodide in contact with starch, when a violet color is developed in the sensitized paper. Unfortunately the

---

<sup>1</sup> See *Belgique Horticole*, Vol. 35, 1885, p. 227.

<sup>2</sup> See *Transactions American Climatological Association*, Vol. 5, p. 118.

discovery of important sources of error has destroyed the value of observations made in this manner. Other substances in the air have been found to act as reducing agents; secondly, the color after having appeared may be altered or destroyed by substances, such as sulphurous acid and many organic substances. Again, the test acts only in a moist atmosphere and, besides that, varies in intensity according to the amount of the wind, so that, in a way, it is a measure of humidity and of wind.

A more recent test, mentioned by Huggard as more sensitive, depends upon the use of what is known as tetra-paper, but is also considered uncertain. The full name of this reagent is tetramethylparaphenylendiamin paper. Notwithstanding the unsatisfactory nature of these tests, the conclusion seems to be accepted that ozone is more abundant in May and June and least abundant in December and January; more abundant in the forests and the seashore and in mid-ocean and least abundant in towns where it commonly cannot be detected. The following quotation is from page 332 *et seq.* of Vol. 1, Watts' Dictionary of Chemistry:

Very little is known respecting the proportion of ozone in the atmosphere, or of the circumstances which influence its production. The ozonometric methods hitherto devised are incapable of affording accurate quantitative estimations. Air over marshes or in places infested by malaria contains little or no ozone. No ozone can be detected in towns or in inhabited houses.

Houzeau determines the relative amount of ozone in the air by exposing strips of red litmus paper dipped to half their length in a 1 per cent solution of potassium iodide. The paper in contact with ozone acquires a blue color from the action of the liberated potash upon the red litmus. The iodised litmus paper is preferable to iodised starch paper (Schönbein's test-paper) which exhibits a blue coloration with any reagent which liberates iodine, *e. g.*, nitrous acid, chlorine, etc. From observations made with iodised litmus paper Houzeau concludes that ozone exists in the air normally, but the intensity with which it acts at any given point of the atmosphere is very variable. Country air contains at most  $\frac{1}{350000}$  of its weight or  $\frac{1}{700000}$  of its volume of ozone. The frequency of the ozone manifestations varies with the seasons, being greatest in the spring, strong in summer, weaker in autumn, and weakest in winter. The maximum of ozone is found in May and June, and the minimum in December and January. In general, ozone is more frequently observed on rainy days than in fine weather. Strong atmospheric disturbances, as thunder storms, gales, and hurricanes, are frequently accompanied by great manifestations of ozone. According to Houzeau, atmospheric electricity appears to be the most active cause of the formation of atmospheric ozone.

It has been found that the air immediately above the tree tops and at the margin of the forest is richer in ozone than that of the interior, where a portion of it is utilized by the decaying vegetation. Ozone certainly aids in purifying the air by oxidizing animal or

vegetable matter in process of decay and by uniting with the gases produced by their decomposition. It can, therefore, be found in considerable amounts where the air is particularly pure. This amount rarely exceeds one part in 10,000. "There is somewhat more ozone on mountains than on plains and most of all near the sea. Water is said by Carius to absorb 0.8 of its volume of ozone."<sup>1</sup>

This statement by Mr. Russell seems to us extraordinary in view of the minute quantity contained in the atmosphere and apparently needs confirmation, especially in view of Russell's next statement that a great excess of ozone is destructive to life, and oxygen containing one two-hundred and fortieth part of ozone is rapidly fatal, and further, that even the ordinary quantity has bad effects in exacerbating bronchitis and bronchial colds, and some other affections of the lungs.

Ozone is not found in the streets of large towns or usually in inhabited rooms, but in very large, well ventilated rooms it is sometimes, though rarely, detected. According to Russell it may be formed on the slow oxidation of phosphorus and of essential oils in the presence of moisture. When produced by electric discharges its pungency of odor is said to make it easily perceptible when present only to the extent of one volume in 2,500,000 volumes of air and the smell may sometimes be noticed on the sea beach.

Since the discovery of ozone by Schönbein, not much has been learned about the actual origin of this allotropic form of oxygen. Its presence in and near forests and living plants has undoubtedly supported the popular view that the air of the forests is particularly healthful and that living plants in our apartments are likewise beneficial.<sup>2</sup>

The existence of hydrogen peroxide in air was first established by Meissner in 1863, but we have no knowledge of the proportion in which it is present. All information as to its relative distribution is obtained from determinations of its amount in rain water and snow. The proportion seems to vary, like that of ozone, with the seasons of the year and with the temperature of the air. It is not improbable that the amount of hydrogen peroxide in air is greater than that of ozone, and it is possible that many so-called ozone manifestations are in reality due to peroxide of hydrogen. Watts' Dictionary of Chemistry.

<sup>2</sup>See J. M. Anders: *House Plants as Sanitary Agents*, Lippincott & Co., 1887.

A recent paper by Sawyer, Beckwith and Skolfield<sup>1</sup> of the Hygienic Laboratory of the California State Board of Health, is one of the latest researches which discredit the claim made for ozone as a purifier of air. During recent years circulars have been issued in great numbers by manufacturers of apparatus stating that ozone is a "necessity" for the destruction of infectious germs and bacterial life, for the sterilization of air in operating rooms for the purification of air in homes of persons suffering from contagious diseases and for giving to offices and homes the invigorating air of the country, seashore and mountains.<sup>2</sup>

How false these claims are can readily be seen from the systematic work of these investigators, the details of which we cannot give here but to which the reader is referred. Among their conclusions are the following:

During these tests certain physiologic effects of the "ozone" were noticed by the experimenters after they had been working around the machines. The immediate effect of inhaling the diluted gas was a feeling of dryness or tickling in the nasopharynx, and sometimes the irritation was felt in the chest. If the exposure was prolonged, watering of the eyes, and occasionally a slight headache, resulted. The smell of the "ozone" and its irritation was much more noticeable to persons who came suddenly under its influence than to those who were continuously exposed.

1. The gaseous products of the two well-known ozone machines examined are irritating to the respiratory tract and, in considerable concentration, they will produce edema of the lungs and death in guinea-pigs.

2. A concentration of the gaseous products sufficiently high to kill typhoid bacilli, staphylococci and streptococci, dried on glass rods, in the course of several hours, will kill guinea-pigs in a shorter time. Therefore these products have no value as bactericides in breathable air.

3. Because the products of the ozone machines are irritating to the mucous membranes and are probably injurious in other ways, the machines should not be allowed in schools, offices or other places in which people remain for considerable periods of time.

4. The ozone machines produce gases which mask disagreeable odors of moderate strength. In this way the machines can conceal faults in ventilation while not correcting them. Because the ozone machine covers unhygienic conditions in the air and at the same time produces new injurious substances, it cannot properly be classed as a hygienic device.

Another paper even more elaborate than this was published at the same time by Edwin O. Jordan, Ph. D., and A. J. Carlson, Ph. D.,

<sup>1</sup> The Alleged Purification of Air by the Ozone Machine. Journ. Amer. Med. Ass., Sept. 27, 1913, p. 1013.

<sup>2</sup> See Amer. Journ. Physiologic Therapeutics, Nov.-Dec., 1911.

of Chicago.<sup>1</sup> This investigation was carried on at the suggestion of and under a grant from the Journal of the American Medical Association. Their experiments were carried out (1) to determine the germicidal action of ozone on pure cultures under the conditions commonly used in testing disinfectants, and (2) to determine the effect of ozone on the ordinary air bacteria. They found, after a long series of experiments detailed in full in their paper, that no surely germicidal action on certain species of bacteria could be demonstrated by the usual disinfection tests with amounts of gaseous ozone ranging from 3 to 4.6 parts per million. The alleged effect of ozone on the ordinary air bacteria, if it occurs at all, is slight and irregular even when amounts of ozone far beyond the limit of physiologic tolerance are employed.<sup>2</sup> The toxication of strong concentrations of ozone through injury to the lungs was marked. Even in moderate amounts it produced an irritation of the sensory nerve endings of the throat and a headache due to irritation, corrosion and consequent hyperemia of the frontal sinuses. Consequently the use of this poisonous gas as a therapeutic agent is either valueless or injurious.

#### USE OF FOREST RESERVATIONS FOR SANATORIA

We cannot leave the subjects of forests and forest air without strongly advocating the use of forests and especially State and Governmental forest reserves for institutions, hospitals, and camps for the tuberculous. The State of Pennsylvania has large forestry reservations, amounting at present to 1,000 square miles in 23 counties, and maintains a State School of Forestry, where young men are in training for its forest service. Acting under liberal forest laws, Dr. J. T. Rothrock, then State Forestry Commissioner, in 1903, announced that citizens of Pennsylvania are entitled to the privilege of using the forestry reservation of the state under proper restrictions as a residence while regaining health and recommended it especially to those in need of fresh air treatment of tuberculosis. In the spring of that year Dr. Rothrock, with State aid, started the construction of a few small cabins for the use of such patients and called it the South Mountain Camp Sanatorium.<sup>3</sup> This is situated

<sup>1</sup> Ozone: Its Bactericidal Physiologic and Deodorizing Action. (Journ. Amer. Med. Ass., Sept. 27, 1913, Vol. 61, pp. 1007-1012).

<sup>2</sup> This is corroborated by the recent article by Konrich, Zur Verwendung der Ozone in der Lüftung. (Zeitschr. Hyg., 1913, Vol. 73, 443.)

<sup>3</sup> Charities and Commonwealth, Dec. 1, 1906. Journ. Amer. Med. Ass., 1907. Journal of the Outdoor Life, Jan., 1907, and Feb., 1908.

in Franklin County, Pennsylvania, in the southern tier of counties where the state owns 55,000 acres. The altitude of the camp is 1,650 to 1,700 feet. It is now the site of the great State Sanatorium known as Mont Alto with a capacity of over 1,000 patients.

At first the patients were obliged to provide and to prepare their own food, but the legislature afterward appropriated enough to enable the management to furnish food, and the results were better than before. Only patients in the incipient stages were admitted, and of the 141 so cared for (up to the year 1908) about 75 per cent were either much improved or cured. The charge to the patients was one dollar per week for all supplies and services, excepting washing and the care of their cabins and their persons. The large forestry reserve allows of an indefinite extension of this method of dealing with the disease, and the small expense seems to point to it as a way to provide for the large class of patients who must be cared for in the incipient stages if the disease is to be checked and its victims restored to society as safe and potent factors in industrial progress. Dr. Rothrock, who has just closed twenty years of distinguished service to the state in the forestry commission, believes that the forest reservations furnish an answer to the further problem of how to care for the consumptive whose disease is arrested, but whose financial condition demands that he must still be cared for until able to return to his home. Pennsylvania has nearly a million acres of forest reservation, much of which needs replanting with young trees. To do this requires a large number of men, and the task of raising and transplanting trees is mostly light outdoor labor, well suited to the convalescent consumptive. In addition, there are various forms of woodcraft, such as basket making and the manufacture of small rustic articles that could easily be carried on under healthful conditions in the forests. The example of Pennsylvania suggests the propriety of other states taking similar steps and providing for the large number of consumptives who need care in an inexpensive and at the same time effective manner.

The United States Government should establish without delay large forest reserves in the Eastern, Middle, and Southern States. The White Mountains of New Hampshire and the Southern Appalachians should be placed under a system of Federal protection. It is encouraging to note that by a recent decision (November, 1913) of the Courts of New Hampshire the way is opened for the condemnation of mountain land in that State and indemnity has been awarded private owners for land so taken.

The United States has 165,000,000 acres of national forests and France and Germany combined, 14,500,000 acres.

The site of a model sanatorium for tuberculosis has the purest air or air nearly devoid of floating matter. It is only on very high mountain tops or in mid ocean, or in the Polar ice fields that we can have air free from suspended matter. The good results obtained in the higher Alpine sanatoria and in long sea voyages, in given cases of tuberculosis, are attributable in some degree to this absence of irritating or polluted atmosphere. In the more northern sanatoria, of which the Adirondack Cottage Sanitarium is a type, the long winter in which snow covers the ground for possibly five months, is always recognized as the best season for patients. The gain in health acquired during one winter equals that of two summers. The added freedom which the snow covering provides against dust and other atmospheric impurities may have its hygienic influence for the cure of tuberculosis.

#### MICRO-ORGANISMS IN RESPIRATORY PASSAGES

It is interesting to learn something of the fate of micro-organisms when inhaled by a person in health or by those whose respiratory passages are already suffering from irritation or disease. It has been calculated that upward of 14,000 organisms pass into the nasal cavities in one hour's quiet respiration in the ordinary London atmosphere.<sup>1</sup> Tyndall showed by his experiments with a ray of light in a dark chamber that expired air, or more exactly the last portion of the air of expiration is optically pure. In other words, respiration has freed the inhaled air from the particles of suspended matter with which it is laden. These experiments coincide with those of Gunning of Amsterdam in 1882 and those of Strauss and Dubreuil in 1887. Grancher has made many experiments with the expired air of phthical patients and has never found in it the tubercle bacillus or its spores. Charrin, Karth, Cadéac, and Mallet have had corresponding results.

These germs are probably all arrested before reaching the trachea; they halt in the upper air passages. The interior of the great majority of normal nasal cavities is perfectly aseptic. On the other hand the vestibules of the nares, the vibrissæ lining them and all crusts formed there are generally swarming with bacteria. All germs are arrested here and the ciliated epithelium rapidly ejects them.

---

<sup>1</sup> On Researches by Drs. St. Clair Thomson and R. T. Hewlet. *Lancet*, January 11, 1896.

By experiments on the mucous membrane of the dorsal wall of the pharynx, Thomson and Hewlet found that a particle of wet cork was conveyed at the rate of 25 mm. or one inch per minute.

Wurtz and Lermoyez have published researches on the action of nasal mucus upon the anthrax bacillus and they hold that it exerts a bactericidal influence on all or nearly all pathogenic agents in different degrees of intensity.

Thomson and Hewlet corroborate this to the extent of saying that the nasal mucus "is possessed of the important property of exerting an inhibitory action on the growth of micro-organisms." Their experiments upon each other were very ingenious and highly interesting. They were able to demonstrate that in ordinary air of the laboratory under the conditions observed, 29 moulds and nine bacterial colonies developed; whereas after passing through the nose the air contained only two moulds and no bacteria.

On another occasion they found in nine liters of laboratory air, six moulds and four bacterial colonies, while the same quantity of air after passing through the nose exhibited one mould and no bacteria. Thus they show that practically all, or nearly all, the micro-organisms of the air are arrested before reaching the naso-pharynx; probably a majority are stopped by the vibrissæ at the very entrance to the nose and those which do penetrate as far as the mucous membrane are rapidly eliminated. They state that the nasal mucus is an unfavorable soil for the growth of organisms and in this it is aided by the ciliated epithelium and lacrymal secretion.

#### COMPOSITION OF EXPIRED AIR

Dr. D. H. Bergey in 1893-4 made some experiments in the Laboratory of Hygiene of the University of Pennsylvania under the provisions of the Hodgkins Fund of the Smithsonian Institution which are pertinent to this subject.<sup>1</sup> These were conducted to ascertain whether the condensed moisture of air expired by men in ordinary, quiet respiration, contains any particulate organic matters, such as micro-organisms, epithelial scales, etc. The expired breath was conducted through melted gelatin contained in a half liter Erlenmayer flask, for twenty to thirty minutes. The gelatin was then hardened

---

<sup>1</sup>J. S. Billings, S. Weir Mitchell, and D. H. Bergey: *The Composition of Expired Air and Its Effects on Animal Life*. Smithsonian Contributions to Knowledge, Vol. 29 (Publication 989), Washington, 1895. This investigation seemed to disprove the renowned experiments of Brown-Séguard and D'Arsonval in 1887.

by rolling the flask in a shallow basin of ice-water, thus distributing the culture in a thin layer over the bottom and sides of the flask.

These cultures were kept under observation for 20 to 30 days. About 150 cc. of gelatin was used for each experiment. The glass tube (b) of the apparatus used, which served for the entrance of the expired air, was inserted far enough to just impinge on the fluid culture medium in the flask, so that the air produced a slight agitation of the fluid in passing through the apparatus. The tube of entrance (b) is provided with a bulb-shaped enlargement which serves to retain any saliva that may flow into the tube. The tube (c) is closed with cotton so as to prevent the entrance of micro-organisms from this side of the apparatus, and a similar cotton plug is inserted in *b* when the apparatus is not in use.

Apparatus for Determining the Presence of Bacteria in Expired Breath.

It was found that the organisms developed in the cultures were all of the same character—a small yellow bacillus, common in laboratory air. When special precautions were taken to sterilize the apparatus with dry heat for an hour previous to introducing the gelatin, besides the subsequent sterilization of the gelatin, the results were negative—no growths developed. If, after standing in the working room for several days, it was found that the culture medium was sterile, the expired breath was then conducted through the apparatus and the culture was kept under observation (for the specified time in the table) at the room temperature. The nature of the organisms that developed in the first two experiments, and the absence of any growth in the others, make it probable that they developed from spores that survived the fractional sterilization of the culture medium. It is improbable that they were carried in the expired breath. Dr. Bergey also made a careful examination of the fluid condensed from the expired air with high powers, both in hanging drops and in six dried and stained preparations, but nothing resembling bacteria or epithelium was found.

The conclusion was reached that there is no evidence of a special

toxicity of the expired air. Billings, Mitchell, and Bergey say, in the monograph referred to, that the injurious effects of such air observed appeared to be due entirely to the diminution of oxygen, or the increase of carbonic acid, or to a combination of these two factors. They consider that the principal, though not the only, causes of discomfort to people in crowded rooms are excessive temperature and unpleasant odors.

We shall see, further on, that later studies show that the relative proportions of oxygen and carbonic acid are not *per se* such important factors.

Dr. Milton J. Rosenau, professor of preventive medicine and hygiene in Harvard Medical School, said in his recent address<sup>1</sup> on "Ether Day" at the Massachusetts General Hospital:

One of the fallacies that has fallen is the relation of the air to the spread of infection. The virus of most communicable diseases was believed to be in the expired breath, or exhaled as emanations of some sort from the body. These emanations were said to be carried long distances—miles—on the wind. The easiest, and therefore the most natural way, to account for the spread of epidemic diseases was to consider them as air-borne. Nowadays the sanitarian pays little heed to infection in the air except in droplet infection, and the radius of danger in the fine spray from the mouth and nose in coughing, sneezing and talking is limited to a few feet or yards at most. The more the air is studied the more it is acquitted as a vehicle for the spread of the communicable diseases.

It was a great surprise when bacteriologists demonstrated that the expired breath ordinarily contains no bacteria. Most micro-organisms, even if wafted into the air soon die on account of the dryness, and especially if exposed to sunshine. The relation of the air to infection is nowhere better illustrated than in the practice of surgery. At first Lister and his followers attempted to disinfect the air in contact with the wound by carbolic sprays. Now the surgeon pays no heed to the air of a clean operating room, but ties a piece of gauze over his mouth and nose, and also over his hair, to prevent infective agents from falling into the wound from these sources.

How complicated this entire subject is we can readily see from the review<sup>2</sup> made by Dr. Henry Sewall, of Denver, of recent experimental studies by Zuntz, Haldane, Rosenau and Amoss, Heymann, Paul, Ercklentz and Flügge, Leonard Hill and others. This review deserves to be read carefully. It sums up our latest knowledge and leads to some surprising conclusions. After describing the Black Hole of Calcutta, in which one hundred and forty-six Europeans

<sup>1</sup> Boston Medical and Surgical Journal, November 6, 1913.

<sup>2</sup> On What do the Hygiene and Therapeutic Virtues of the Open Air Depend? by Henry Sewall, Ph. D., M. D. (Journ. Amer. Med. Ass., Jan. 20, 1912).

were confined on the night of June, 1756, and only twenty-three survived, he shows that numberless observations have all led to the one conclusion that prolonged confinement in close air tends to lower vitality and increase the incidence of certain infections, especially pulmonary tuberculosis. However, it was found many years ago that animals and men can tolerate without distress an increase of carbon dioxide in the air far beyond any concentration which it is likely to acquire under the worst conditions of crowding, provided the oxygen tension is maintained at a high level. Zuntz and Haldane and his associates show that the normal excitement of the respiratory nerve-center depends on the accumulation within it of carbon dioxide, a waste product, which it is a prime object of respiration to remove. Sewall refers to Brown-Séquard and D'Arsonval's work and, as bearing on it, the very recent work of Rosenau and Amoss.<sup>1</sup> These workers condensed the vapor of human expiration and injected the liquid into guinea-pigs. No symptoms followed this procedure. But after an appropriate interval of some weeks a little of the blood-serum from the person supplying the moisture was injected into the same animals. The outcome was an unmistakable anaphylactic reaction. According to current beliefs the result showed that the expired air must have contained proteid matter which sensitized the pigs toward proteids in the blood of persons from whom the first proteid was derived. The authors offer, as yet, no opinion as to whether the proteid in the expired air possesses hygienic significance.

Prof. Sewall finds a suggestive analogy in the physiologic relations of carbon dioxide which it is one of the chief objects of respiration to remove. Added to air in sufficient percentage it is deadly to animals, yet so far from its being useless in the body, Haldane and Priestley found that it must form four to five per cent of the alveolar air for the maintenance of normal respiratory movement, and a considerable lowering of its tension in the body would be followed by speedy death. Boycott and Haldane note that the subjective sense of invigoration and well-being excited by cold weather is associated with a high tension of carbon dioxide in the alveolar air.<sup>2</sup> After summarizing the experiments of Heyman, Paul,

---

<sup>1</sup> Organic Matter in the Expired Breath (*Journal of Medical Research*, 1911, Vol. 25, 35).

<sup>2</sup> Haldane and Priestley: The Regulation of the Lung Ventilation (*Journal of Physiology*, 1905, Vol. 27, p. 225).

Boycott and Haldane: The Effects of Low Atmospheric Pressure on Respi-

and Ercklentz in Flügge's laboratory<sup>1</sup> which seem to show that, in people both well and sick, chemical changes in the character of the air in inhabited rooms exercise no deleterious effect on the health of the dwellers. Dr. Sewall reviews Leonard Hill's work which shows that the motion of the air in the experimental chamber by means of electric fans almost entirely annulled the sense of discomfort.<sup>2</sup> He then cites the astonishing experiments of F. G. Benedict and R. D. Milner<sup>3</sup> who kept a subject for twenty-four hours in a chamber, the air of which held an average carbon dioxide content of 220 parts per 10,000 or over seventy times the normal, together with a reduction of oxygen to less than 19 per cent. The humidity was kept down and the temperature held uniform. The subject of the experiment suffered no discomfort.

Boycott and Haldane, referred to above, express the opinion that "the alveolar carbon dioxide tends to a lower level in warm weather" and that this diminution in the alveolar carbon dioxide is associated with a feeling of warmth of a rather unpleasant kind rather than with any absolute point on the thermometer; they hold that the rise in the carbon dioxide tension is associated with the general exhilaration and stimulation produced by cold air.

And now comes Leonard Hill, the physiologist, of London, who with his staff at the London Hospital conducted several noteworthy experiments which he described before the Institution of Heating and Ventilating Engineers in March, 1911.<sup>4</sup> In view of the fact that

the London health authorities insist that in factories the percentage of carbon dioxide must not rise above the usual amount allowed, say ten parts in ten thousand, he remarks that the regulations do not prescribe any limitations of the wet-bulb temperature adding that while carbon dioxide does not do any harm whatever a wet-bulb temperature of 75° F. is very bad and ought not to be tolerated in any factory. All the current teaching of the hygiene of ventilation runs on the subject of chemical purity of the air; but according to Prof. Hill the essential thing in ventilation is heat, not chemical purity. It does not matter if there is 1 per cent more carbon dioxide and 1 per cent less of oxygen. In the worst ventilated rooms there is not 1 per cent less oxygen. The only effect of an excess of carbon dioxide is to make one breathe a little more deeply. A much higher amount has to be attained to have any toxic effect. As to organic impurities derived from respiration there is no physiologic evidence of their toxicity or that they are of any importance except as an indicator of the number of bacteria in air. The way to keep air best from the physiologic point of view is shown by the following experiment performed by Hill at the London Hospital: Into a small chamber which holds about three cubic meters he put eight students and sealed them up air tight. They entered joking and lively and at the end of 44 minutes the wet bulb temperature had risen to 83° F. They had ceased to laugh and joke and the dry bulb stood at 87° F. They were wet with sweat and their faces were congested. The carbon dioxide had risen to 5.26 per cent and the oxygen had fallen to 15.1 per cent. Hill then put on three electric fans and merely whirled the air about just as it was. The effect was like magic; the students at once felt perfectly comfortable, but as soon as the fans stopped they felt as bad as ever and they cried out for the fans. These and other experiments related, according to Hill, show that all the discomfort from breathing air in a confined space is due to heat and moisture and not to carbon dioxide. Even after five repetitions of the experiment there were no after-effects, such as headache. The obvious inference is that the air must be kept in motion to avoid bad effects. The open air treatment of disease is not altogether a matter of fresh air, but the constant cooling of the body by the circulation of air which makes us eat more and promotes activity. This leads to the general strengthening of the body because the blood is not only circulated by the heart but by every muscle in the body.

There cannot be efficient circulation without constant movement

and activity. If there is constant cooling by ventilation, then a person is kept more active and the general health is improved.

As Dr. M. J. Rosenau said in his recent address :

Thus our entire conception of ventilation has changed, owing to the fact that we now do not believe that fresh air is particularly necessary in order to furnish us with more oxygen or to remove the slight excess of carbon dioxide. It is plain that it is heat stagnation that makes us feel so uncomfortable in a poorly ventilated room rather than any change in the chemical composition of the air. It has been made perfectly clear from the work of Flügge that one of the chief functions of fresh air is to help our heat-regulating mechanism maintain the normal temperature of the body. It is necessary to have some 2,000 to 3,000 cubic feet of air an hour to maintain our thermic equilibrium—just the amount that was formerly stated to be necessary to dilute the carbon dioxide and supply fresh oxygen. The practice of ventilation, therefore, has not altered so much as has our reason for attaching importance to clean, cool, moving air, which has completely changed.<sup>1</sup>

The foregoing résumé is perhaps not complete without mentioning the recent work of Prof. Yandell Henderson, of Yale University, who has brought forward his "Acapnia" theory (acapnia meaning diminished carbon dioxide in the blood). He says:<sup>2</sup>

We have really at the present time no adequate scientific explanation for the health-stimulating properties of fresh air and the health-destroying influence of bad ventilation. . . . The subject needs investigating along new lines rather than a rehearsal of old data.

Dr. Crowder's recent experiments<sup>3</sup> also furnish additional evidence against the theory that efficient ventilation consists in the chemical purity of the air, in its freedom from "a toxic organic substance." Even were a poisonous protein substance present in the expired air—a fact no experimenter has yet been able to demonstrate—the human organism under every-day conditions is apparently well able to adjust itself to the reinhalation of this hypothetical substance, since a considerable quantity of the expired air is always taken back into the lungs.<sup>4</sup>

We consider that experiments like these demonstrate most valuable and practical truths and that is our excuse for introducing them so particularly in this place. When we consider that the average man exhales from 9,000 to 10,800 liters of air in twenty-four

---

<sup>4</sup> Editorial in Journ. Amer. Med. Ass., Nov. 29, 1913. See also page 108.

hours<sup>1</sup> it would indeed be a terrible situation if it were true that the expired breath could convey pathogenic or other bacilli. The millions of bacilli which we take into the air passages are arrested in the air passages and for the most part mercifully destroyed by the secretion.<sup>2</sup> In any event we have the assurance that the expired air is free from micro-organisms. With reference to tuberculosis this means that if healthy persons are exposed only to the expired air of tuberculous subjects no infection can occur. Only through bacilli contained in the sputum or in tiny drops of moisture coughed by the patient is the disease communicated; and it is further probable that, as in the case of other infectious organisms, when once received into the nose and mouth and upper air passages, they quickly lose their activity or are soon extruded. (See page 13 *et seq.*)

#### ATMOSPHERIC IMPURITIES

In view of these facts it would scarcely seem necessary to state that for the treatment of all respiratory diseases and especially for the treatment of infections such as tuberculosis, which invades the larynx and the lungs, or for the treatment of patients whose throats and lungs owing to other infections, such as tonsillitis, pneumonia, or influenza, may be specially susceptible, no city air can be considered favorable. It is our duty to provide as nearly as possible air with a very low bacterial content such as may be obtained in forests or in the neighborhood of the seashore.

#### COAL AND SMOKE

Aside from the presence of bacteria in the air of cities and towns there are other impurities which are of great disadvantage to tuberculous patients. The prevalent use of soft, or bituminous coal in Great Britain and America, especially in manufacturing centers, undoubtedly shortens human life and hastens many a consumptive to his end. Volumes have been written on this subject and most valuable contributions have been made by Dr. J. B. Cohen, of Leeds, Mr. Francis A. R. Russell, Henry de Varigny and others, published in connection with the Hodgkins Fund.<sup>3</sup>

See also "The Influence of Smoke on Acute and Chronic Lung Infections," by Wm. Charles White, M.D., and Paul Shuey, Pittsburg. Trans. Amer. Climatological Association, 1913.

Dr. William Charles White and Paul Shuey, of Pittsburgh, have recently made a study of the influence of smoke on acute and chronic lung infections, selecting pneumonia and tuberculosis as a cause of death in Pittsburgh, St. Louis, Portland, Oregon, St. Paul, Cincinnati, Chicago, Philadelphia, New York, New Orleans, Richmond, Cleveland, San Francisco, Indianapolis, Minneapolis, Memphis, Boston, Mobile, and Los Angeles. They plotted the number of smoky days per year, 1907 to 1912, with the smokiest cities first and so on to the least in the order indicated above. The mortality for white population and total population and other data are noted on the accompanying chart. This study is in some respects unsatisfactory, because of the difficulty of getting data as to smoky days. The conclusion was that if we except Portland and St. Paul there is a general tendency of the tuberculosis death rate to rise as the number of smoky days in the city decreases. On the other hand, it will be seen that there is a general tendency for the number of deaths from pneumonia to fall as the number of smoky days in the city decreases. In this instance, also, Portland, St. Paul, and Boston must be excepted. All this needs confirmation.

It is a matter of common knowledge that coal miners are liable to a disease called fibrosis, anthracosis, or miners' consumption, in which the lungs receive and retain coal dust, which penetrates every nook and cranny of the lungs and adds one more element of danger to a most hazardous occupation. But we have it on the authority of Sir Frederick Treves that he had seen the lungs of many persons, who had lived in London, which were black from their surface to their innermost recesses. Such a condition, in his opinion, not only made it more difficult to resist disease, but started disease, and it was entirely due to dirt and soot inhaled. The black fog of London owes its color to coal smoke, which gives it its filthy, choking constituents, and kills people by thousands. Experiments showed that during a bad fog six tons of soot were deposited to the square mile.<sup>1</sup>

---

<sup>1</sup> Some six hundred years ago, the citizens of London petitioned King Edward I to prohibit the use of "sea coal." He replied by making its use punishable by death. This stringent measure was repealed, however, but there was again considerable complaint in Queen Elizabeth's reign, and the nuisance created by coal smoke seems to have been definitely recognized at this period. Since this time there has been continual agitation, together with much legislation, both abroad and in this country. In the seventeenth century, King Charles II adopted repressive measures in London, and in the present century anti-smoke crusades have been frequent. In fact, the smoke problem will undoubtedly continue to demand attention until it is either

Death-rates per 10,000 for Pneumonia and Tuberculosis in Eighteen Cities, 1907-1912. The number of smoky days are noted, for each year (heavy line). Total death-rates and population per acre noted.

The Lancet undertook by means of a system of gauges of its own design to estimate the annual deposit in London of all adventitious matter from the atmosphere. In the city proper it was calculated to be nearly five hundred tons to the square mile or about four and a half pounds per acre each day. Were it mere dirt it would not be so serious, but it is charged with gases and fluids of a deleterious character such as sulphates, chlorides, ammonia, and carbon that is more or less oily and tarry. One of the experts employed by the Meteorological Council in connection with the County Council of London, found that the sulphur contents of the coal ranged from one to two per cent and that from half a million to a million tons of sulphuric acid were diffused in the air every year. The loss to property from this erosive influence he estimated at about five and a half million pounds sterling. The effect upon health was a more elusive question, but stress was laid on the rise in death rate during foggy weather in which coal smoke plays a prominent part. Owing to the activity of the Coal Smoke Abatement Society, under the presidency of Sir William Richmond, atmospheric conditions are greatly improved, and it is claimed that there is a steady diminution in the number and density of the black fogs.

In an article on London as a Health Resort and as a Sanitary City, by S. D. Clippingdale, M. D., *Trans. Royal Society of Medicine*, February, 1914, there is an interesting historical account of London air and fog, with a bibliography.

#### CARBON DIOXIDE

Parallel conditions are observed in cities like Leeds, Liverpool, Manchester, and Glasgow, and in less degree in cities like Pittsburgh, Cincinnati, Chicago, Cleveland, and St. Louis, during periods of comparatively calm, and of heavy and humid atmosphere. Egbert<sup>1</sup> states that "it has been calculated that for every ton of coal burnt in London something like three tons of carbon dioxide are produced," and as the city's coal consumption is over 30,000 tons per diem, its atmosphere must receive the enormous daily contamination of about 300 tons of soot and 90,000 tons of carbonic acid every day! How important, then, the adoption of practical means to abate the smoke nuisance! Engineers assure us that such means

---

entirely solved by the abolishment of the use of solid fuel or by the installation of devices and methods which shall prevent the formation of smoke in furnaces, regardless of the nature of the fuel.

<sup>1</sup> Seneca Egbert: *A Manual of Hygiene and Sanitation*, Philadelphia, 1900. p. 74.

are perfectly feasible and economical. It does not need an engineer to assure us that they are hygienic.

Prof. Charles Baskerville, of the College of the City of New York, has vigorously attacked the problem of smoke and other air impurities. He shows<sup>1</sup> that the sticky properties of soot are due to the tar contained in it. This tar adheres so tenaciously to everything that it is not easily removed by rain. In large manufacturing districts, particularly in those where bituminous coal is used as fuel, vegetation is blackened, the leaves of trees are covered and the stomata are filled up, thus inhibiting the natural processes of transpiration and assimilation. In addition, the soot is frequently acid and the deposition of acid along with soot is probably one of the principal causes of the early withering which is characteristic of the many forms of town vegetation.

#### SULPHUR DIOXIDE

Aside from the solid material which pollutes the atmosphere of cities, there are correspondingly enormous quantities of noxious gases which are equally injurious to persons with tubercular disease or other diseases of the respiratory tract. Mention has already been made of the vast amounts of carbonic acid gas generated by furnaces, not to speak of the quantities exhaled by human beings. The production of this carbon dioxide by the combustion of coal offers a definite measure of the production of sulphur dioxide. These two gases have the same origin and the measure of one is the measure of the other. Recent studies by Prof. Theodore W. Schaefer, who has made many observations of the air of Kansas City during fogs, tend to show that the presence of sulphur dioxide has an unfavorable effect on persons suffering from bronchitis, pharyngitis, pneumonia, and asthma. In January, 1902, the heavy fogs occurring in St. Louis, Missouri, caused serious injury to the throat and lungs of prominent singers and in an action brought against the city and its chief smoke inspector, it was alleged that owing to the additional presence of smoke, suffocating gases, and acid, the health of the complainant was injured. In a mandamus proceeding it was asked that the authorities be compelled to abate the smoke nuisance.

Prof. Schaefer has used the data mentioned previously as to the output of carbonic acid in London and states that he finds that at least 2,700 tons of sulphur dioxide are generated daily in that city and pass into surrounding atmosphere. This gas, after uniting with

---

<sup>1</sup> Medical Record, New York, November 23, 30, 1912.

the oxygen and aqueous vapor of the air, is converted into sulphuric acid.<sup>1</sup>

The presence of sulphur in coal, or in iron pyrites contained in coal, is responsible for this acid product and Prof. Schaefer believes that sulphur dioxide, being a very heavy gas, with a specific gravity of 2.25, is alone capable of creating a fog, or is at once shown when it is brought in contact with the atmosphere, from which it absorbs aqueous vapor, causing dense, heavy fumes. The dust or carbon particles, coming in contact with this acid vapor, enhance its gravity materially.

Prof. Baskerville some time ago made a number of determinations of the sulphur dioxide content of the air of New York city. Stations were established throughout greater New York city, including high office buildings, parks, subways, stations, and railroad tunnels; and very variable results, as might be expected, were obtained. The determinations may, in part, be thus summarized:

| <i>Locality</i>                             | <i>SO<sub>2</sub> in parts in a million</i> |
|---|---|
| Elevated portion of city, near a high stack | 3.14  |
| Various parks                               | 0.84 (maximum; others negative)             |
| Railroad tunnels                            | 8.54—31.50                                  |
| Subway                                      | None  |
| Downtown region                             | 1.05—5.60                                   |
| Localities near a railroad                  | 1.12—8.40                                   |

In 1907, the residents of Staten Island, as well as some on Long Island, complained of the noxious nature of the air wafted over from various plants in New Jersey. This induced the Department of Health of the City of New York to investigate the air and vegetation in the vicinity of the Borough of Richmond, Staten Island, and some of the results obtained are given below by permission of the Department.

| <i>Substance</i>      | <i>Impurity</i>                            |
|-----------------------|--|
| Air                   | Trace of sulphuric acid                    |
| Air                   | 0.0066 per cent. SO <sub>2</sub> by weight |
| Air                   | Trace of sulphuric acid                    |
| Grass (three samples) | Sulphuric acid present                     |
| Grass                 | 0.24 per cent SO <sub>3</sub>              |
| Grass                 | 0.70 per cent SO <sub>3</sub>              |
| Leaves                | 0.19 per cent SO <sub>3</sub>              |
| Leaves                | 0.28 per cent SO <sub>3</sub>              |
| Soil                  | 0.0015 per cent SO <sub>3</sub>            |

<sup>1</sup>Theodore W. Schaefer: The Contamination of the Air of our Cities with Sulphur Dioxide, the Cause of Respiratory Disease. Boston Medical and Surgical Journal, July 25, 1907.

These results do not really give us anything definite, as the comparative factor is absent.

Fog usually collects in the lower portions of a city, especially in depressed localities known as hollows, where it remains until dispersed by air currents. The well-known increase of mortality in cities during the continued presence of heavy fog with these additional contaminations have been recorded and commented upon for years. The heavy, suffocating, poisonous quality of sulphur dioxide is well known and has been the subject of several investigations. In general, it may be said that the chief symptoms of poisoning with sulphurous acid are those of irritation of the mucous membranes. Even in five parts in 10,000 it acts as an irritant, causing sneezing, coughing and lacrymation, bronchial irritation and catarrh (Cushny). It is also credited with causing pneumonia and Prof. Schaefer notes its power to produce asthma.<sup>1</sup> Undoubtedly it would aggravate pulmonary and laryngeal tuberculosis and either delay or prevent a cure under the conditions described.

#### AMMONIA IN THE AIR

This gas is constantly present in the atmosphere, but in very minute quantities. Fifty years ago Boussingault and, later, Schloesing made careful investigations of this impurity of the atmosphere and devised ingenious methods of estimating its amount in air and rain water. It usually exists only in combination with carbonic or nitric acid; very little is free. Water absorbs it freely and it has been estimated that in France the annual rainfall brings to the earth in the form of nitrogen nearly 5 kilograms per acre. The presence of ammonia indicates organic putrefaction. Its amount does not usually exceed a very few parts per million. It is usually perceptible, as we all know, in and about stables.

As far as any relation to tuberculosis is concerned, ammoniacal air has for us only a remote interest. At one time it was strongly advocated as a cure for pulmonary consumption and perhaps some historic details may be of interest here.

Dr. Thomas Beddoes, of London, published in 1803, "Considerations on a Modified Atmosphere in Consumption Cases," and strongly advocated residence in a cow stable for such cases. One of his patients was Mrs. Finch, a daughter of Dr. Joseph Priestley,

---

<sup>1</sup> This accords with the conclusions of W. C. White and Paul Shuey, *loc. cit.*

The relation of Sea Fog to Tuberculosis is considered in the next chapter, page 52.

famous for his epoch-making discovery of Oxygen. The patient, from the description given, had a well-marked case of pulmonary tuberculosis in the second or third stage. She was placed in a stable 14 by 20 feet and 9 feet high, and her bed was in a small recess a few inches above the ground of the stable, where two or three cows were kept. The temperature was maintained at 60° to 70° F. Mrs. Finch remained in this cow house nearly all the time from the autumn of 1799 until the spring of 1800. In a letter, dated August 15, 1800, the patient wrote, "I am happy in being able to say that my chest continues perfectly well; and from the difference of my feelings now, and some years back, I am more than ever a friend of the cows. I avoid colds and night air; and by rides in the country am anxious to brace myself against winter and the necessity of a sea voyage."

#### OXYGEN FOR TUBERCULOUS PATIENTS

Shortly after the discovery of oxygen, physicians were stimulated to try the effect of various gases in the treatment of phthisis. Fourcroy and Beddoes both observed the effects of the inhalation of oxygen and found that it accelerated the pulse and respiration, and, as they believed, increased inflammatory action so that they concluded that its effect was prejudicial. Beddoes held that in phthisis there is an excess of oxygen in the system and consequently, that free air was injurious to the patient. He says in the essay quoted previously:<sup>1</sup> "As it seemed to me hopeless to propose residence in a cow house, I advised that the patient should live during the winter in a room fitted up so as to ensure the command of a steady temperature. This advice was followed. Double doors and double windows were added to the bed room. The fire place was bricked up round the flue of a cast iron stove for giving out heated air." What a contrast to the fresh air cure of the present day! But the doctor persisted in his plan of treatment until the patient died.

The amount of oxygen present in the atmosphere, 20.938 per cent, is precisely adapted to the needs of animal life and the same proportion of oxygen is preserved in the atmosphere everywhere, without regard to altitude.<sup>2</sup> It has been found that animals die if the ratio of oxygen is artificially decreased by as much as twenty-five per

---

<sup>1</sup> Thomas Beddoes: *Observations on the Medical and Domestic Management of the Consumptive*. American edition, Troy, 1803, p. 42.

<sup>2</sup> Analyses by Gay-Lussac of Air Collected at 7,000 meters; and observations by Dumas and Boussingault.

cent; but Paul Bert<sup>1</sup> also showed that too much oxygen was equally prejudicial to life and, indeed, poisonous, animals dying in a super-oxygenated atmosphere as soon as their blood contains one-third more than the normal ratio of oxygen, because in such an atmosphere the hemoglobin of the red blood corpuscles is saturated with oxygen—a fact which never occurs under normal conditions—and a proportion of this gas then dissolves in the serum of the blood. Here lies the danger, for the tissues cannot withstand the presence of free, uncombined oxygen and death follows. The question immediately arises: Why do the tissues require combined oxygen and why does free oxygen kill them? No one knows. Henry de Varigny, who deals with this subject with reference to aerobic and anaerobic organisms deals with this curious fact and acknowledges our limited knowledge on this point. He states, however, that while a certain increase in the ratio of oxygen results in death, lesser increases of a temporary character may be beneficial. Every poison kills, doubtless, but there are doses which not only do not kill, but even confer benefit and improve health.

Lorrain Smith has shown that oxygen at the tension of the atmosphere stimulates the lung-cells to active absorption; at a higher tension it acts as an irritant, or pathologic stimulant, and produces inflammation.<sup>2</sup>

As far as the respiratory processes are concerned the respiration of pure oxygen takes place without disturbing them for even in an atmosphere of pure oxygen animals breathe as though they were respiring normal atmospheric air.<sup>3</sup>

Sir Humphrey Davy believed that when pure oxygen was inspired there is no more chemical change induced than occurs when atmospheric air is breathed; in other words, let the vital actions be a constant quantity, the addition of oxygen to the inspired air does not materially increase vital transformation. Fifty years ago there was great confusion in the minds of otherwise intelligent observers and false reasoning led them into grave errors. Those who, like Beddoes, believed that there was too much oxygen in the system held that the inhalation of air containing carbonic acid was the proper plan of treatment and this theory of hyper-oxidation was revived

by Baron von Liebig, who recommended that in phthisis the respiratory action should be lessened.<sup>1</sup>

The Boston Nutrition Laboratory of the Carnegie Institution of Washington has undertaken a most painstaking series of investigations bearing on this subject. They include an examination of the comparative oxygen-content of uncontaminated outdoor air under all conditions as to wind direction and strength, temperature, cloud formation, barometer, and weather. In addition, samples of air were collected on the Atlantic Ocean, on the top of Pike's Peak, in the crowded streets of Boston, and in the New York and Boston subways. The results of the analyses of uncontaminated outdoor air showed no material fluctuation in oxygen percentage in observations extending over many months and in spite of all possible alterations in weather and vegetative conditions. The average figures are 0.031 per cent of carbon dioxide and 20.938 per cent oxygen. The ocean air and that from Pike's Peak gave essentially similar results.

The extraordinary rapidity with which the local variations in the composition of the air are equalized is accentuated by the observations on street air in the heart of the city, where the contaminating factors might be expected to be of sufficient magnitude to affect perceptibly the analytic data. Only the slightest trace of oxygen deficit is shown, with a minute corresponding carbon-dioxide increment. Observations such as these tend to demonstrate the extent of the diffusion of gases and the establishment of equilibrium by air-currents.

Most unexpected are the figures in regard to the extremely small extent to which the air was vitiated in the modern "tube" or subway, even during "rush" hours. There was, on the average, a fall of 0.03 per cent in oxygen accompanied by a rise of 0.032 per cent in the carbon dioxide. Professor Benedict points out that while the measurement of carbon dioxide has been taken as an index of good or bad ventilation, the fact that the proportion of oxygen is actually lowered by an increase in the carbon dioxide has never before been clearly demonstrated. As a result of this, the determination of the content of carbon dioxide in the air, which can be made with ease and accuracy, suffices to establish the approximate percentage of oxygen. For every 0.01 per cent increase in the atmospheric carbon dioxide one may safely assume a corresponding decrease in the percentage of oxygen. Aside from minor fluctuations ex-

---

<sup>1</sup> See Edward Smith: *Consumption, Its Early and Remediable Stages*. Blanchard and Lea, Philadelphia, 1865.

plained above, it may now truly be said that "the air is a physical mixture with the definiteness of composition of a chemical compound."<sup>1</sup>

Since the introduction<sup>2</sup> into medical practice of oxygen compressed in cylinders its use has been tried in tuberculous cases, but no satisfactory results have been obtained and its use is discontinued, except, so far as we know, in the hands of charlatans.

The inhalation of oxygen gas may not *per se* exert any curative action on a tuberculous lung, but that fact should not lead us to the conclusion that the voluntary respiration of an increased quantity of air is not beneficial. It is stated that the air in the central parts of the lungs is richer in carbonic acid than that found in the larger tubes and hence deep inspiration followed by deep expiration causes a larger amount of the air richer in carbonic acid, to be exhaled. From this the conclusion is drawn that increased chemical change will result, for if the carbon dioxide be removed from the air cells its place will be filled by quantities of the same gas which will escape from the blood. Furthermore, the removal of carbon dioxide from the blood facilitates and makes possible those metabolic changes which with a supply of suitable food improve nutrition.

Nowadays we often speak of oxygen as synonymous with atmospheric air and in this sense we give it a prominent place in pulmonary therapeutics. We are tempted to reproduce the placard of an old boot-maker and chiropodist of fifty years ago which read:

The best medicine! Two miles of oxygen three times a day. This is not only the best, but cheap and pleasant to take. It suits all ages and constitutions. It is patented by Infinite Wisdom, sealed with a signet divine. It cures cold feet, hot heads, pale faces, feeble lungs and bad tempers. If two or three take it together it has a still more striking effect. It has often been known to reconcile enemies, settle matrimonial quarrels and bring reluctant parties to a state of double blessedness. This medicine never fails. Spurious compounds are found in large towns; but get into the country lanes, among green fields, or on the mountain top, and you have it in perfection as prepared in the great laboratory of nature.

Before taking this medicine . . . should be consulted on the understanding that corns, bunions, or bad nails, prevent its proper effects.

---

<sup>1</sup> See the recent monograph by Benedict, F. G.: The Composition of the Atmosphere with Special Reference to Its Oxygen Content, Carnegie Institution of Washington, Publication 166, 1912. Review in Journ. Amer. Med. Ass., Jan. 25, 1913.

<sup>2</sup> The late Dr. Andrew H. Smith, of New York, was the first in the United States to use Oxygen in medical practice, 1860. "Oxygen gas as a Remedy in Disease," A. H. Smith, 1870.

The old London boot-maker had more wisdom than most of the doctors of his time.

### CHAPTER III. INFLUENCE OF SEA AIR; INLAND SEAS AND LAKES.

#### SEA VOYAGES

The value of sea air in tuberculosis has been discussed *pro* and *con* for ages and, like the tide, there is an ebb and flow of sentiment regarding its value in the treatment of tuberculosis. Undoubtedly there is, at present, a stronger belief in the efficacy of sea air in the various forms of tuberculosis than at any previous time. This is especially true as regards tuberculosis of the bones, the tuberculosis of children and in the important class of cases termed fibroid phthisis.

Aretaeus, about 250 B. C., recommended sea voyages for the cure of consumption, and 300 years later Celsus advocated voyages from Italy to Egypt, if the patient were strong enough. Celsus was a layman whose learning was truly encyclopedic, but only his medical writings have survived. When the Roman sufferer from tuberculosis was not able to make the sea voyage to Egypt he was sometimes advised to pass a large portion of his time sailing on the Tiber.<sup>1</sup>

At Kreuznach, Ems, and other continental resorts, salt inhalations are given to patients with scrofulous and chronic bronchial affections. Instead of trusting to sea breezes the patients are taken to halls where saline particles are present in a higher percentage than they can ever be at the sea side. They inhale the salt-laden air and make use of pulverization apparatus. Hours are spent in the open air near the "evaporating fences" so as to inhale salt air at interior stations. At Ems this treatment is carried out in pneumatic chambers capable of holding ten people in compressed atmosphere for about  $1\frac{3}{4}$  hours.

Sea air is of acknowledged purity as to micro-organisms, dust and adventitious gases. As previously remarked, there is at sea a maximum of ozone and a minimum of all foreign deleterious substances. (See page 9.) Without considering, as yet, the amount of watery vapor in the air of the ocean and other features of ocean air such as its movement and temperature, we recognize some physical contents such as a minute quantity of sodium chloride, iodine and bromine as characteristic of sea air when contrasted with air from any other

<sup>1</sup>"Opus est, si vires patiuntur, longa navigatione, coeli mutatione, sic ut densius quam id est, ex quo discedit aeger, petatur; ideoque aptissime Alexandriam ex Italia itur." Celsus, De Med. lib. 111, Cap. 22.

locality. The wind carries aloft fine particles derived from the crests of the waves and this saline matter from sea water and foam is constantly present near the surface and is carried for miles inland.<sup>1</sup> It is well known that plants near the seashore have a perceptible coating of saline matter which modifies their growth.

As far as the present subject is concerned we have to deal with the influence on the tuberculous processes exerted by a marine climate. This can be obtained by undertaking sea voyages or by a residence on islands, or on the seaboard.

Ocean voyages were formerly strongly advocated as a means of cure in tuberculosis and were given an extended trial especially by English physicians. The constant commercial intercourse between England and her possessions all over the world made the practice easy and the results have been carefully weighed. Before the days of steam the typical ocean voyage from London to China or India involved vastly different conditions, as to time, route and accommodations. Some features will always be the same. Seasickness, the confined air of cabins, storm and wet will remain to harrass and terrify the traveler. But the clipper ships of the past are now, for the most part, doing duty as coal barges and the steam "tramp" and ocean liner carry the cargoes of the world.

After ruling out the tramps, cattle ships, and the coasting schooners, we have left a few sailing vessels still engaged in the East India trade and the fast liners. Modern systems of ventilation and cold storage have corrected some of the great disadvantages of the past and the presence of competent surgeons on board all the larger passenger steamers make the trip comparatively safe for a tuberculous patient if the necessity arises for him to make the voyage. But as a strictly therapeutic measure such trips are not to be recommended and in this we are supported by nearly all good authorities.<sup>2</sup>

---

<sup>1</sup>Two illustrations from a storm at Blackpool, England, are supplied by the courtesy of Dr. Leonard Molloy.

<sup>2</sup>Huggard, A., Handbook of Climatic Treatment, London, 1906, says: "Sea voyages were formerly in great repute for persons with phthisis; but it is now recognized that, except in certain well-defined instances they generally do harm. Only slight or mild cases without fever and without active symptoms, are likely to benefit. The patients most suitable for a sea voyage are those in whom the disease has become partly or entirely arrested." Dr. Burney yet doubts whether phthisis at any stage is benefited by ocean travel. Prof. Charteris, of Glasgow, approves of a sea voyage in the early stage of phthisis in a young person, but after that stage all experience testifies that degeneration proceeds more rapidly on sea than on shore and the patient, if he reaches land, only does this to find a grave far away from the surroundings of friends and home.

Dr. W. E. Fisher, for many years surgeon to the Pacific Mail Steamship Co., while observing that patients affected with chronic diseases, such as phthisis, dyspepsia, etc., are not so liable to seasickness as others, states that a large percentage of tuberculous patients stand the sea voyage badly. Dr. Fisher's experience relates to the trip from New York to San Francisco by way of Panama. During the first part of the voyage until the Bahama Islands are reached, the invalid experiences bracing weather. From that point to the Isthmus and thence up the coast during the long voyage of three weeks or more, a distance of nearly three thousand miles, the temperature averages  $90^{\circ}$  in the shade and on many days rises as high as  $95^{\circ}$  or  $96^{\circ}$  F. This occurs during the winter months and is the direct cause of deaths on the voyage or shortly after arrival on the California coast.

Dr. R. W. Felkin, of Edinburgh, says:<sup>1</sup> "Fifteen years ago I used to advocate sea voyages in my lectures on Climatology in Edinburgh, with great confidence; now I am more cautious. I do not send phthisical patients to sea as I once did. The risk of spreading infection is, to my thinking, too serious to be incurred. I well remember once sending two sisters to Australia; the elder suffered from phthisis; the younger was healthy. The elder certainly did gain some temporary benefit, but the younger sister and also a cabin companion became infected, and all three girls were in their graves within a year of their return to this country. I am sure that occupying a joint cabin as they did caused the mischief."

Dr. F. Parkes Weber, of London, takes a more hopeful view.<sup>2</sup> He says that sea voyages are often useful in the milder and quiescent forms of pulmonary tuberculosis, provided the patient's general condition be such as otherwise to fit him for life on shipboard. "Long voyages are to be preferred to all other methods of treatment in the case of male patients who have a taste for the sea, who are strong physically, or who possessed an originally strong constitution and were infected by 'chance' or when weakened by overwork, worry, improper hygienic conditions, or acute diseases."

In pulmonary tuberculosis complicated by syphilis, or syphilitic phthisis, as it was formerly designated, a marine climate seems to be particularly suitable.<sup>3</sup>

---

<sup>1</sup> *Journal of Balneology and Climatology*, January, 1906.

<sup>2</sup> F. Parkes Weber: *System of Physiologic Therapeutics*, Vol. 3, p. 87, Philadelphia, 1901.

<sup>3</sup> See Roland G. Curtin, *Trans. Amer. Climatological Ass.*, Vol. 4, p. 31.

The vicissitudes of sea-travel, the narrow cabins and the difficulty of obtaining a suitable diet, even such common requisites as milk and eggs, should be enough to condemn this plan. Tuberculosis patients ought not to travel more than is absolutely necessary. Imagine the bacteriological condition of a consumptive's stateroom, for instance, at the end of a month's voyage! What sea-captain or steward would ever put such a cabin into a sanitary condition for the next passenger?

The author has some experience of life at sea under both sail and steam, although he has never taken very prolonged voyages. Taking into account the character of the food supply and the necessity of at least sleeping in small cabins and probably spending days in them, with uncertain medical attention; and, besides this, the dangers of various kinds that pertain to seaports, the author feels bound to condemn sea voyages for the tuberculous in any stage.

*"Non mutant morbum qui transeunt mare."*

#### MARINE CLIMATE OF ISLANDS

It is far better for the tuberculous patient to remain on *terra firma* than to traverse the sea. Whatever is of value in the sea air can be obtained in islands such as Ireland, the Isle of Man, the Isle of Wight, Nantucket, the Isles of Shoals, Newfoundland, Long Island, the Bahamas, the Canaries, the Philippines, Samoa, and many other islands.

Just as in the case of sea voyages, there are concomitant influences, many of which are notoriously unfavorable, that in themselves over-balance any possible advantage from sea air. Take, for instance, the problem as it presents itself in Ireland or the Isle of Man.

Among the various countries of the world Ireland stood fourth in the order of mortality from tuberculosis, being exceeded by Hungary, Austria, and Servia. During the last thirty-five years the mortality in Great Britain has been reduced one-half among females and one-third among males but, until 1907, there had been no such fall in Ireland.

Sir John Byers, of Belfast, in his address<sup>1</sup> entitled "Why is Tuberculosis so Common in Ireland?" characterized its prevalence in that country as "appalling." Among the nine causes which are assigned for this condition of affairs attention is first directed to the *damp climate*. An investigation of places with rather worse con-

---

<sup>1</sup> The Lancet, January 25, 1908. See also Alfred E. Boyd, M. B.: Tuberculosis and Pauperism in Ireland, British Journ. Tuberculosis, July, 1908, p. 159.

ditions of climate led Sir John to say on this point: "I cannot, therefore, admit that there is much in the dampness of the atmosphere as a cause of tuberculosis in Ireland." Sir William Osler takes precisely the same ground and pointed out at the opening of the Tuberculosis Exhibit in Dublin, that Cornwall, with a much damper atmosphere than that of Ireland, was so free from the disease that consumptives were sent there. In Cardiff, Wales, with a damp climate and with the ground water in many places near the surface in the gravel and with the lower part of the town on a stiff marine clay, very retentive of moisture, the tuberculosis death rate for 1906 was only 1.20 per 1,000. On the other hand in Belfast, with a smaller rainfall (34.57 inches as against 42.43 inches) the mortality was more than twice as much, or 2.77 per 1,000. The figures for 1906 were:

|   | Rainfall<br>inches | Death rate<br>from<br>tuberculosis<br>per 1000 |
|---|--------------------|--|
| Manchester, notoriously damp, foggy and smoky.... | ....               | 1.82   |
| Liverpool .....                                   | ....               | 1.82   |
| London .....                                      | ....               | 1.42   |
| Cardiff, Wales .....                              | 42.81              | 1.20   |
| Bolton, England .....                             | 42.43              | 1.11   |
| Belfast, Ireland .....                            | 34.57              | 2.77   |
| Cork .....  | ....               | 4.53   |
| Dublin, Ireland .....                             | 27.73              | 2.91   |
| North Dublin, Ireland .....                       | ....               | 4.70   |

After taking up in turn dampness of soil, emigration as a cause for tuberculosis, the asserted susceptibility of the Irish to tuberculosis, poverty and social position, food and drink and industries, and after weighing them carefully they were all discarded as insufficient causes of this mortality. The prime cause was declared to be *want of Sanitary Reform* and the *prevalent domestic or home treatment of the advanced cases of pulmonary tuberculosis*.

Since 1907 an encouraging decline in the mortality from tuberculosis has been noted. Whereas the rate for both sexes throughout Ireland was 273.6 per 100,000 in 1907 it had dropped by gradual stages to 215.2 in 1912. Sir William Thompson, the General Register for Ireland, justly attributes this well marked decrease during the past six years to the exertion of Her Excellency, the Countess of Aberdeen.<sup>1</sup>

<sup>1</sup>Trans. National Association for the Prevention of Consumption and Other Forms of Tuberculosis, 5th Annual Conference, London, August 4 and 5, 1913. See also Sir John Moore, *Interstate Medical Journ.*, April, 1914.

Sir William shows that this decrease indicates 17,000 fewer people suffering from tuberculosis in Ireland in 1912 than there were in 1907. This corresponds to a decrease of nearly one-fifth of the total number of cases of tuberculosis. He seems hopeful that within the next few years the death-rate from tuberculosis in Ireland will not be above the average in other countries.

Undoubtedly hygienic and philanthropic measures are entitled to the credit for this marked improvement and it gives us pleasure to note in this connection the remarkable work of Her Excellency, the Countess of Aberdeen. This noble woman founded in 1907 the Women's National Health Association of Ireland and a vigorous campaign was started which soon roused the whole country to a sense of responsibility in matters of public health and, in particular, to measures necessary for the prevention and cure of tuberculosis. The influence of this organization rapidly spread and within eighteen months no less than seventy branches had been opened throughout Ireland, for the most part opened in person by their excellencies, the Lord Lieutenant and Countess of Aberdeen, and now it has 150 branches and 18,000 members.

While undertaking the reduction of infant mortality, the improvement in the milk supply and better school hygiene, the association made a systematic attack on the prevalence of tuberculosis. This included home treatment and its strong ally, the tuberculosis dispensary, on a plan similar to that originated by Sir Robert Philip, of Edinburgh; it included sanatorium treatment; and it provided special treatment for advanced cases of tuberculosis. In this phase of the work the association had the benefit of £145,623. through the provisions of the National Insurance Act. Charitable Americans also contributed handsomely toward the erection of sanatoria now comprising one thousand beds, the maintenance of dispensaries and of depots for the supply of pasteurized milk.<sup>1</sup>

It is interesting to note that the Association also lent its support to the formation of an "Irish Goat Society," believing that the best way to meet the scarcity of milk experienced in many parts of Ireland is to encourage the keeping of a good breed of milking goats. Then, too, through the administration of the Laborer's Acts nearly fifty thousand cottages with garden plots ranging up to one acre have been built for rural laborers by rural sanitary authorities at an outlay of over £8,000,000.

We have cited this remarkable campaign of the anti-tuberculosis

---

<sup>1</sup> The late Mr. R. J. Collier and Mr. Nathan Straus.

movement in Ireland to show how close are its relation to the broader field of general hygiene and sanitation and to show that such work pays; and furthermore what great service one person of noble birth, by her foresight, solicitous care and untiring devotion, can initiate and carry out. As Prof. Thompson says: There is no doubt that it will rank as one of the greatest philanthropic efforts of our time.

Take the Isle of Man. This island in the Irish Sea has a population of over ten thousand and for six hundred years has been singularly free from the admixture of English, Irish, or Scotch blood. The island has a more equable climate than any other part of the British Isles. The mean annual temperature is 49° F. There is comparative absence of frost, fog, or snow. But careful records since 1880 show that the Manx tuberculosis death rate is about double that on the mainland.<sup>1</sup>

|                         | 15.06   | 11.39 per 10,000 |

The Bahamas and Bermuda in the Atlantic Ocean have a sub-tropical marine climate that experience shows to be far too relaxing and enervating for tuberculous patients.

The Philippines and all other tropical islands are likewise entirely unsuited for tuberculous patients for the same reasons.<sup>2</sup> Newfoundland, with a harsh, damp, colder air, is equally bad.

Dr. Newsholme, of Brighton, President of the Epidemiological Section of the Royal Society of Medicine, in an elaborate inquiry into the principal causes of the reduction of the death rate from phthisis in different countries, came to the conclusion that the one

<sup>1</sup> Charles A. Davies, M. D.: Tuberculosis in the Isle of Man (Tuberculosis, London, Oct., 1900).

<sup>2</sup> According to Dr. Issac W. Brewer, U. S. A., "Notes on the Vital Statistics of the Philippine Census of 1903," American Medicine, Oct., 1906, the death rate from tuberculosis is one-third that in the United States.

common factor present in all cases where a fall was noted was the segregation of the patients in hospitals or sanatoria. In each country where the institutional has replaced the domestic relief of destitution there has been a reduction of the death rate from phthisis which is roughly proportional to the change.

As to the cause, then, of the spread of tuberculosis, we shall find that it probably always lies in ignorance, indifference and other moral or sociologic causes, and, in many of the cases cited, not to climatic or atmospheric conditions.

Our opinion of sea air is fortunately not confined to that of the high seas or even that of islands. The sea air sweeps the mainland and, as we know, modifies the climate of all adjacent portions of the Continent. The great source of atmospheric moisture is found ultimately in the oceans. The invisible watery vapor and the visible clouds are carried inland and deposit their water over the Continent. The monsoons which are most highly developed in India and other parts of Asia, prevail also in Texas and on the Pacific coast of the United States. These seasonal winds are of great importance from a climatic standpoint and hence should be taken into account in reference to the climatic treatment of tuberculosis.<sup>1</sup> During the summer and autumn in India these seasonal winds sweep inland from the sea and deluge the country with rain. This amounts, in the Khasi Hills, 200 miles north of the Bay of Bengal, to between 500 and 600 inches a year and reaches its maximum at points about 1,400 meters, 4,600 feet, above sea level.

Fortunately in the United States these seasonal winds, while present, are not so dominant as climatic factors. We are more concerned in the present study with the diurnal winds of the seashore. The sea breeze which tempers the heat of our coasts is a distinctly beneficial feature of the shore and not only tends to moderate the heat of the summer day, but sweeps inland for fifty or a hundred miles the pure ocean air and provides all the desirable features of a marine climate.

#### ARCTIC CLIMATE

Passing still farther north we have the Arctic climate. It is marine or insular and cold. Arctic voyages have been proposed for the treatment of tuberculosis and, as adjuncts to the voyage, a summer sojourn in the northern fjords of Greenland. A trip of this

---

<sup>1</sup> See William Gordon: *The Influence of Strong, Rainbearing Winds on the Prevalence of Phthisis*, H. K. Lewis, London, 1910, *Observations in Devonshire*.

kind has been seriously planned by Dr. Frederick Sohon, of Washington, D. C., but has never yet been carried out.<sup>1</sup>

It is a significant fact that Arctic explorers from Dr. Elisha Kent Kane down, including General A. W. Greely, Admiral Peary, Mr. W. S. Champ, Mr. Herbert L. Bridgman, the late Dr. Nicholas Senn, and others comment on the healthfulness of the Polar climate. Dr. Sohon made two voyages with Commander Peary, in 1896 and in 1902, and states his opinion that in summer the Arctic regions are entirely suitable for, and beneficial to, the tuberculous, and that the unequalled natural advantages for a cure can be practically utilized. Few understand the fascination which the Polar regions undoubtedly exert on all who enter that charmed circle. The expressions used by Arctic explorers seem so extravagant to the average mind. The late Professor Senn says: "Nature there lends such efforts toward prophylaxis, as to leave no need for therapeutics."<sup>2</sup>

The air of the Arctic regions is free from dust and germs. It is not, in itself, responsible for any disease which may be carried into Arctic settlements by ships' crews, or by means of the migration of animals or birds. Colds and catarrhal conditions are conspicuously absent. There is no pneumonia. The only "Arctic Fever" is that which explorers are almost sure to contract on their first visit and which has an annual periodicity. It is not a self-limited disease, as Admiral Peary can testify after nearly fourteen consecutive summers in the Polar regions.

Another feature of the atmosphere in the Arctic is absolute clearness and abundance of sunshine. Dr. Sohon, in 1902, exposed dishes of agar and introduced into culture tubes pebbles, bits of vegetation and water from the ground and from pools at Commander Peary's winter quarters. Of six dishes exposed for from one-half to two hours, two were sterile and four gathered only a common white mould (*P. glaucum*). Only the hay bacillus was obtained from the pebbles. Water yielded the hay bacillus, *B. liquefaciens*, *B. fluorescens* and an unclassified non-pathogenic saprophytic rod organism.

<sup>2</sup>Nicholas Senn: Medical Affairs in the Heart of the Arctics (Journal American Medical Association, 1905, Vol. 45, pp. 1564, 1647).

The atmosphere has a bracing quality and is always credited with developing a prodigious appetite. It is pointed out that a taste is developed for the kind of food the tuberculous patient needs, viz., fatty food and meat. The craving for this kind of food is usually accompanied by a corresponding adaptability to digest it and, in healthy subjects, flesh is always gained. Dr. Sohon says that in both of his trips to Greenland he has exceeded his usual maximum weight, gaining the first time thirty pounds in two months, and the second time nineteen pounds in six weeks. In the latter voyage even the crew made an average gain of ten pounds in weight.

A large share of the beneficial influence of any atmospheric change is that which conduces to a good appetite and digestion. In this respect the summer Arctic voyage may fairly claim pre-eminence. With qualities such as these it is natural that, for a portion of the year at least, the merits of the Arctic climate in the treatment of tuberculosis should at least be considered.

An atmospheric feature is its great penetrability for light and especially for the actinic and ultra-violet rays. Tanning of the skin always occurs and sunburn is not uncommon. During summer the sun never sets and, though not very high in the heavens, its generous rays must exert a very beneficial influence on any morbid process, especially of a tubercular type. Arctic plants develop rapidly from seed to flower and seed again in surprising manner and the wild animals seem to be the largest and most vigorous of their kind.

In judging of the weather to be encountered in the Arctic regions, we are too much inclined to recall the harrowing accounts of the ill-fated expeditions of the past; but in the Northern fjords of Greenland, some miles from the coast, or in the protected inland bays, the atmospheric conditions of summer are quite agreeable and are especially suitable for the open air treatment.

The fluctuations of temperature are very moderate. The average minimum temperature between July 28 and September 6, between 69° and 78° north latitude on these Greenland Fjords, was about 38 F.; the average maximum was 49° to 50°. Temperatures as high as 56° were recorded at North Star Bay and about 52° at Etah.

The humidity averaged low. The records were made at 8 a. m. and 8 p. m., and, owing to the constant daylight, are much more representative estimates of relative humidity than in the case of records of relative humidity at those same hours in temperate latitudes.

|                       | Maximum Humidity |         | Minimum Humidity |         | Average |         |
|-----------------------|------------------|---------|------------------|---------|---------|---------|
|                       | 8 a. m.          | 8 p. m. | 8 a. m.          | 8 p. m. | 8 a. m. | 8 p. m. |
| New York .....        | 100              | 95      | 62               | 50      | 81.3    | 74.1    |
| Denver .....          | 90               | 90      | 41               | 13      | 66.1    | 37.1    |
| North Star Bay .....  | 72               | 71      | 56               | 39      | 63.1    | 54      |
| Etah, Greenland ..... | 81               | 70      | 40               | 35      | 57.6    | 52.4    |

The relative humidity was much lower while at anchor in the harbors of Northern Greenland than while en route through the Strait of Belle Isle and off Labrador and in Davis Strait and Smith's Sound.

We have given some attention to this subject on account of the very enthusiastic claims made on behalf of the atmosphere of the Arctic regions during summer treatment of tuberculosis. Although the plans for sending a ship with tuberculous passengers on this voyage failed to be carried out owing to inability to get the necessary permission from the Danish Government to land at the northern ports of Greenland, it is possible that at some future time the attempt will again be made.

The fact that Icelanders and Greenlanders may contract tuberculosis in numbers and may die from it is not to be overlooked; but the filth of winter quarters in the far North and the foul air of these huts is responsible for much of the illness of the native inhabitants. The Eskimo survives the dangers of the winter because he leads a totally different life in summer. It is difficult for those who have never been to the Polar regions to realize what a change is wrought by the advent of constant sunlight. This unique feature of the summer climate contributes to health and energy. The atmosphere, free from all germs and dust, bracing in its quality, is a strong stimulant to bodily functions as gain in weight testifies.

As a practical measure for the treatment of tuberculosis Arctic voyages have not yet been proved to be beneficial, although there is some presumptive evidence in their favor and, in view of the abundance of proof that the disease can be successfully combated at numberless places on the continent, such expeditions will scarcely meet with favor.

#### FLOATING SANATORIA

In 1896, Mr. M. O. Motschoutkovsky<sup>1</sup> advocated floating sanatoria for patients with incipient tuberculosis. These specially fitted vessels were to be shifted from port to port according to the season so as to get the most favorable climatic conditions.

<sup>1</sup>The Lancet, April 4, 1906, p. 939.

OPEN AIR CLASS ON FERRY BOAT "SOUTHFIELD," EAST RIVER, NEW YORK CITY. SLEEPING HOUR  
Courtesy of Dr. J. W. Brannan

OPEN AIR SCHOOL FOR TUBERCULOUS CHILDREN. FERRY BOAT "SOUTHFIELD," BELLEVUE HOSPITAL. SEE PAGE 43

The vicissitudes of sea-travel, the narrow cabins and the difficulty of obtaining a suitable diet, even such common requisites as milk and eggs, ought to be enough to condemn this plan. Tuberculous patients ought not to travel more than is absolutely necessary. Old ferry boats have been recently utilized in New York as classrooms for tuberculous scholars. The ferry boat "Southfield" has been equipped for this work through the Miss Spence's School Society under the direction and courtesy of Bellevue Hospital in cooperation with Dr. John Winters Brannan and Dr. J. Alexander Miller.

There are three classes on the "Southfield"; two for pulmonary cases of about thirty-six children; these classes being part of the regular Bellevue Clinic work and entirely supported by Bellevue.

The third class is for tuberculous cripples with about twenty children. The cost of nurses and special equipment for this class together with incidental expenses is borne by the Spence School Society.

The teachers for all three classes are supplied by the New York Board of Education so that they are a part of the regular school system.<sup>1</sup>

Owing to the fact that these old ferry boats seem to answer a useful purpose and in view of the reported use by the Italian Government of three discarded men-of-war as floating sanatoria in the treatment of tuberculous patients, a request was made to the Navy Department of the United States for similar ships by the Fourth International Congress on School Hygiene at Buffalo, N. Y., August 29, 1913, in a resolution, a portion of which is as follows:

WHEREAS, It has been demonstrated in New York and other cities that discarded vessels lend themselves admirably to transformation into all-year-round hospitals and sanatoria for consumptive adults, sanatoria for children afflicted with joint and other types of tuberculosis, and into open air schools for tuberculous, anemic, and nervous children;

*Resolved*, That the fourth International Congress on School Hygiene petitions the United States Government to place at the disposal of the various States of the Union as many of the discarded battleships and cruisers as possible to be anchored according to their size in the rivers or at the seashore and to be utilized by the respective communities for open air schools, preventoria, sanatorium schools for children, or hospital sanatoria for adults.

The Secretary of the Navy, however, for the following very good reasons, declined.

---

<sup>1</sup> See Buffalo Medical Journal, 1907-8, Vol. 63, 41.

I am of the opinion that battleships are not suitable for floating sanatoria. This opinion is based on the following reasons.

The cost of maintaining a battleship in proper sanitary and structural condition is very high.

Battleships, particularly the older types, have very limited deck space, and this is so cut up by hatches, turrets, davits, cranes and winches that there are few spaces large enough for a cot. The cost of removing these obstructions would be equivalent to that of building more suitable floating hospitals.

The ventilation in the enclosed spaces of these vessels is so poor that it often has an unfavorable effect on those chosen especially for their health and vigor. Its effect on those already diseased could not be favorable. The openings are very small and admit but little sunlight; it is necessary to use artificial light for a large part of the day. To correct these conditions would involve great expense, even if it were possible of accomplishment.

The passages are narrow, the ladders steep and the hatches small, making transportation of the sick very difficult.

Very respectfully,

JOSEPHUS DANIELS,  
*Secretary of the Navy.*

Under the title "Una nave-scuola-sanatorio per fanciulli predisposti" Federico di Donato has urged this plan in Italy but up to the present the Italian Government has not assented.

The remark has been made that: "If the right sort of ship could be sent to the right place in the right kind of weather with the right sort of patients, a great deal of good might result."

#### SEASIDE SANATORIA FOR CHILDREN

In the United States notable attempts have been made to utilize sea air in treating tubercular disease in children. Individual cases have been treated by sea air, but on a larger scale we should mention the experience of two institutions.

In 1872, Dr. William H. Bennett, of Philadelphia, established the Children's Seashore House at Atlantic City, New Jersey. This institution is open during the entire year, and in 1912 more than 3,500 mothers and children were cared for. Among the first patients admitted to the Institution at its inception were the hospital children suffering from tubercular diseases of the bones, glands, and joints. The wonderful improvement wrought in such cases by the sea air led to a steadily increasing demand for their admission, and now throughout the year seventy beds are set apart for their care and treatment.

The most notable and most recent attempt in the United States to treat cases of tuberculosis of the bones, joints and lymph nodes is at the Sea Breeze Hospital at Coney Island on the Atlantic

Ocean, ten miles from New York City. This was undertaken by the New York Association for Improving the Condition of the Poor. Ten tents were erected on the beach and were opened to children between the ages of two and fourteen on June 6, 1904. These tents had a capacity of fifty patients. In the autumn permanent buildings were occupied and have since been used. While the main reliance has been on fresh sea air and good food, the very best surgical aid has been employed, and for all major operations the children were temporarily removed to hospitals in New York City. This co-operative arrangement is a great advantage to the seashore institution, as the distance is not great and avoids the necessity of enlarging the surgical staff and at the same time provides the highest surgical skill. To avoid mistakes most of the cases admitted are seen by at least one other surgeon besides the attending surgeon. While pulmonary cases are refused the staff admits severe, desperate, and even hopeless cases.

In a recent report by two of the members of the staff<sup>1</sup> there are histories of forty-two cases and illustrations of the methods of treatment; but the noteworthy feature of the report is the prominence given to residence at the seashore as the chief means of cure. The conclusions from seventy-six histories which form a basis of the report are as follows:

(1) The seashore is the best place for treating children with tuberculous adenitis. The children make a better recovery here than elsewhere. Those with adenoids and enlarged tonsils should be submitted to an operation as a start of the cure. Sea air does not permit us to dispense with this.

(2) The seashore is probably the best place for children with tuberculous joints, provided they can have there the same skilled orthopedic care as elsewhere. Their disease runs a somewhat milder and probably a shorter course, and the functional results are better than those obtained elsewhere.

(3) Our results have been largely due to the careful attention (including feeding and nursing) which has been given the children.

(4) Our results justify pushing the work.

(5) A hospital such as this does better work than a public hospital under control of the municipality.

(6) Many cases of co-called bone tuberculosis are in reality syphilis.

We do not know whether there is anything "specific" about the seashore.

---

American Climatological Association*, 1905, p. 107; John Winters Brannan, *Trans. National Association for the Study and Prevention of Tuberculosis*, 1906. Roland Hammond: *Heliotherapy as an Adjunct in the Treatment of Bone Disease*, *Amer. Journ. Orthopedic Surgery*, May and October, 1913.

or whether children simply thrive better and so overcome more quickly their disease.<sup>1</sup>

As to treatment other than diet and fresh air, little need be said. We use plaster when we can in preference to braces. In Pott's disease we use first the Bradford frame, then plaster jackets; in hip joints, the short Lorenz spica. In knee-joint disease after the acute stages, we also use plaster-of-Paris. Patients with large cold abscesses are transferred to the Manhattan hospitals, where their abscesses are opened, wiped out, and sewn up again with proper aseptic precautions.

On January 21st of the present year, 1914, the author revisited Sea Breeze Hospital, Coney Island, New York, in order to see what is being accomplished. Six cases of hip disease were being treated by partial exposure of the body to the sun. The patients were in bed on the balcony with the usual extension apparatus in place. General exposure, beginning with the feet and gradually involving the entire body, is not adopted at Sea Breeze, as a rule, and only the area of abdomen, hip and thigh adjacent to the diseased joint was exposed to the air and sun. Continued cloudy and unfavorable weather had prevented much progress in the newer patients who were then undergoing treatment; others who had been cured of serious tuberculous disease by the open-air method had recently been discharged. The fresh-air system is, however, well carried out, but not upon the naked body as in Switzerland and France.

The temperature on the open balcony next to the wooden wall of the building was 62° F. at noon in the sun. It was the first bright day after weeks of storm and cloud. It is probable that the very encouraging experience of the last two years will lead to the adoption of Rollier's method in all its details as modified by the less favorable climatic conditions of this part of the Atlantic seaboard.<sup>2</sup>

Results at Sea Breeze Hospital in the treatment of tuberculosis of the bones, joints and glands have been so good that the city of New York has acquired a new location with 1,000 feet of beach front on what is known as Rockaway Point, ten miles beyond Coney Island. The plot runs back about 600 feet to Jamaica Bay and cost the city, after condemnation proceedings, \$1,250,000. The plans include an arrangement of grounds and buildings which will involve a total

<sup>1</sup> Charlton Wallace, M. D.: *Surgical Tuberculosis and Its Treatment* (Journal of the Outdoor Life, March, 1913). This author, who is Orthopedic Surgeon to St. Charles' Hospital, Long Island, and the East Side Free School for Crippled Children, New York, says: The author is not in a position to produce scientific proof that sea air is better than country air, but he does believe such to be the case, although there are some individual patients who do better in the country than at the seashore.

<sup>2</sup> Heliotherapy is used at the Crawford Allen Hospital, Rhode Island.

outlay of \$2,500,000 and there will be accommodation for 1,000 patients in the eight pavilions. Contracts for two of these pavilions have been let and will be paid for by a fund raised by the New York Association for Improving the Condition of the Poor. The new hospital will be turned over to the city of New York and will be conducted by Bellevue and Allied Hospitals. The plans include an immense playground running back to Jamaica Bay for the use of the public.

Credit is due to Dr. John Winters Brannan, of New York, president of Bellevue and Allied Hospitals, for much of the great work which has so far taken about nine years to accomplish and for which America will be justly proud.

Encouraged by the success at Sea Breeze, another hospital for surgical tuberculosis in children was started six years ago at Port Jefferson, on the north shore of Long Island, opposite the Sound. The situation is said to be ideal. It accommodates two hundred children and is a handsome fireproof structure. It is called St. Charles' Hospital; it is under the active care of the "Daughters of Wisdom," a Roman Catholic Society. The children, according to Dr. Wallace, receive every physical, mental, spiritual and industrial care necessary to produce good moral men and women. It is an active orthopedic hospital admitting any deserving case and keeping him there until the lesions are healed. Patients in advanced stages of bone tuberculosis are received as well as those with pulmonary complication. Under the good hygienic surroundings at St. Charles' Hospital, the children have shown great improvement in every way. Dr. Wallace adds: "The removal of the diseased bone with the knife is no longer attempted, because such a procedure not only takes away the root from which the bone grows, but also fails to eradicate the affected area. Reliance must therefore be placed on other than cutting methods for local treatment of the affected parts." Immobilization by plaster-of-Paris, properly applied and fresh air on the shore of Long Island Sound, conjoined with every other hygienic aid possible, constitute the line of treatment.

The New York Hospital for Ruptured and Crippled has lately removed to a new site on a hill near the East River, where the outdoor treatment for the tuberculous cripple is carried out as well as it can be in a large city.

In England it has long been customary to send scrofulous children and those with surgical tuberculosis to the eastern and southeast coast. At Margate the Royal Sea-Bathing Hospital, founded by

Lettsom and Latham in 1791, is the oldest institution of the kind in Great Britain, and retains its pre-eminence. There are similar institutions at Brighton, Bournemouth, Folkestone, and Ventnor, Isle of Wight (see plate 12).

The impression prevails at present in England that sea air is the best for these cases. The bracing air suits them perfectly and children with tuberculous bones, joints, or glands can stand a much colder and fresher air than children with pulmonary disease. Sea air improves the general health and keeps nutrition at the highest level. Italy and France, however, take the lead in seashore sanatoria exclusively devoted to tuberculous children. They have been in existence on the Italian shore at Viareggio since 1856, and on the French coast since 1860, and are conducted on a very extensive and systematic scale. The first sanatorium at Berck-sur-Mer was established in 1860 by the city of Paris, and is almost exclusively for children suffering from tuberculous disease of the joints, bones and glands, and has at present considerably over one thousand beds and accommodates children from the poorest quarters of Paris.<sup>1</sup>

Two private hospitals for similar cases are located at Berck-Plage. One was founded by Baron Rothschild and is maintained by his widow and contains 600 beds. Four-fifths of the cases are surgical; one-fifth, medical.<sup>2</sup> The other is in Cazin Perrochaud and accommodates 200. At Pol-sur-Mer there is a similar institution maintained by the city of Lille, which is designed to have 900 beds.<sup>3</sup> At Cannes there is an excellent private institution, the Villa Santa Maria, for the "cure helio-marine des tubercules chirurgicales" under the direction of D. A. Pascal.

Besides these institutions for surgical tuberculosis there are others which are intended mainly for pulmonary tuberculosis. These are located at Hendaye, Ormesson, Villiers-sur-Marne and Noisy le Grand. There are now fifteen sanatoria on the French coast open throughout the year and, in addition, a number open for only a part of the year, containing in all over four thousand beds. In 1904 there were twenty-three Italian hospitals distributed along the Mediterranean and Adriatic shores of Italy, with over ten thousand beds.

These hospitals are said to be closed in winter. (Brannan.) Every other country in Europe, with the exception of Turkey and Greece, has one or more seashore sanatoria for tuberculous children, so that there are as many as seventy-five such hospitals on the shores of Europe. The Argentine Republic has two seashore sanatoria, one established twenty-three years ago with three hundred beds and a new one with five hundred beds.

The plan of treatment at all these institutions is very simple and ought to have been carried out on this side of the Atlantic long ago. The brilliant experience at Sea Breeze, Coney Island, is simply due to a repetition of the methods adopted for decades in France and England. The régime at all these sanatoria is about the same. The patients are kept out of doors all day on the beach or on verandas, which are covered but are open on the front and sides. Four meals a day with unlimited milk are provided. All through the winter the children occupy themselves on the grounds or on the beach; those confined to bed are on the open porches enjoying the sunshine and the sea air, the best tonics in the world, and developing a ruddy color and better general circulation than they have ever known. Their warm hands in the coldest winter weather is the wonder of all who visit them. At night the windows are wide open and the air has practically the same temperature as at any point on the coast, varying from 12° to 40° F. If the snow drifts in at night, as sometimes happens, nobody seems to be the worse. The windows are, however, closed for a half hour morning and evening while the children are being washed and dressed.

The surgeons at Berck-Plage, although engaged in active orthopedic work, are all firmly convinced that residence at the seashore, with the greater part of the twenty-four hours spent in the open air, does more for the children than could be accomplished even in the best appointed hospitals in the cities.<sup>1</sup> One of the surgeons at Margate, after fifteen years of constant work in the wards, states his opinion that the knife plays a very secondary part to climatic and general influences.

For an institution of this kind to attain the highest efficiency one thing seems plain; the patients must be admitted at a very early age, not from six years old and upwards, but as early as two years of age. In this respect the French and American sanatoria have the advantage of the English. The point has been made that at six years

---

<sup>1</sup> Each year during the early part of August vacation clinics are held, which are attended by large numbers of French and foreign physicians.

of age a child with tuberculous disease is often past cure. Much can be done with a tuberculosis case if " caught young."

After serious operations, the surgeons at the seaside sanatoria note that progress is much more rapid when patients can live in the open air and the practical point has been discovered that subsequent dressings of a much more simple character are permissible under the open air régime. For instance, in Metropolitan hospitals the practice of packing and draining wounds has untold terrors for the unfortunate patients. Dr. Charlton Wallace found that at " Sea Breeze " tuberculous sinuses heal more rapidly and permanently when all packing and drainage are omitted and only a sterile absorbent dressing is applied. As the general instability of these patients is such as to cause them almost to collapse at the thought of having their wounds probed and packed, it led him to believe that they would gain strength and local resistance if they were not nervously upset at the time of each dressing. In the beginning, in order to ascertain whether there would be full drainage, comparisons were made of the amount of discharge, with and without the full dressing, and as there was no diminution he concluded that packing or tubing was not essential to drainage. Not only was the danger of infection less, no infected wound being observed, but he found that no sinus healed which still contained pus. This certainly simplifies the treatment of surgical wounds and the credit is given to the favorable atmospheric conditions.

At Sea Breeze the children receive from one to two hours instruction daily, the teachers being furnished by the Brooklyn Board of Education. It has been noted that the educational training given at this Sea Breeze Hospital has a most happy effect on the morals of the patients and at this early age much more can be accomplished in combating vice and ignorance, which constitute the greatest obstacles in dealing with the tuberculosis problem.

(For open air schools for tuberculosis children, Waldschule, etc., see pp. 103-107).

In estimating the value of sea air in non-pulmonary tuberculosis in children, we naturally look to France for some data based on the enormous experience now extending over a period of nearly fifty years. During the last twenty years in France alone 60,000 children have been treated in these sanatoria and Dr. Brannan is authority for the following statement :

|  |             |
|--|-------------|
| Cures, 59 per cent. Decidedly improved.. | 25 per cent |
| Total of favorable results .....         | 84 per cent |
| Cures in Pott's Disease .....            | 32 per cent |
| Cures in glandular tuberculosis .....    | 74 per cent |

These results of the treatment of surgical tuberculosis at seashore sanatoria are much more favorable than in the case of pulmonary tuberculosis, in adults, in corresponding localities (see pp. 71-73).

Nevertheless, the Department of Public Charities of the City of New York has just built and equipped at an expense of \$3,500,000, a new hospital for adults having pulmonary tuberculosis in the second or third stage. The site selected is on the highest point of Staten Island in New York Bay, 400 feet above tide and only five miles from

the ocean. This new addition to New York's equipment has one thousand beds and is called the "Sea View Hospital."

At the Second Annual Meeting of the National Association for the Study and Prevention of Tuberculosis held in Washington in 1906, the following resolution was offered by Dr. John W. Brannan and unanimously adopted:

WHEREAS, Recent experience in Europe and in this country has shown that out-door life in pure air has the same curative effect in surgical tuberculosis as in tuberculosis of the lungs, therefore, be it

*Resolved*, That in the opinion of members of this Association hospitals and sanatoria should be established outside of cities either in the country or on the seashore for the treatment from its incipency, of tuberculosis of bones, joints, and glands in children.

#### SEACOAST AND FOGS

Marine climates naturally include the strictly ocean climate and that of the seacoast. In the former sea air comes from every point of the compass. It is always moist and it is the most equable air that blows; it is of infinite variety from the dead calm of the doldrums to the fierce gales of the North Atlantic.

The atmosphere of the seacoast is naturally modified at times by continental influences. Indeed the characteristic "sea breeze" which springs up in the morning and subsides toward sun-down is brought about by the ascent of heated air back of the coast. The hotter the interior and the more rapidly this air ascends the stronger is the sea breeze which rushes shoreward from the ocean and penetrates for fifty or a hundred miles the adjoining country.

But under other conditions land breezes occur and bring to the shore the Continental atmosphere of a totally different type. These atmospheric conflicts between sea and land involve most interesting meteorological problems; they tend to lessen the equability of the purely marine or oceanic climate. Freezing weather is the product of the Continent and the descent of cold waves from the interior; it brings to our northern seacoast frost and snow for a time, and never trespassing far upon the high seas. The seacoast has thus a mixture of two climates, but the sea air predominates and is never absent very long.

There are well-known places in America and in the British Islands where the sea breeze greatly predominates; Nova Scotia, Cape Cod, and Cape May in the United States; Land's End and the Cornish Coast in England are cases in point. In such exposed situations the air is generally poorly adapted to the tuberculous patient. The air

is said to be "too strong" and certainly for an all-the-year-round residence the capes and headlands are too much at the mercy of high winds which render out-door life disagreeable. About Cape Cod, Nantucket, and Martha's Vineyard there is a peculiar liability to fog which is as unwelcome to the consumptive as it is to the mariner.

The author has had experience with the fogs in these waters and considers it one of the great drawbacks to an otherwise agreeable climate. The summer and early autumn fogs of the eastern Maine coast and of the Bay of Fundy and Nova Scotia are worse in their chilly and penetrating qualities. The towns of Massachusetts on or near the seacoast seem to have somewhat more tuberculosis than those of the interior.

Mr. Hiram F. Mills, of the Massachusetts State Board of Health, has lately published a most painstaking analysis of the mortality from tuberculosis in all the towns and cities of that state.<sup>1</sup>

He shows that there are sixty cities and towns bordering on the sea having a total population of about one-third of the entire state, or 1,293,625, in which the average death-rate per 100,000 for the five years, 1908-1912, was 135. During this period the rate for the entire state was 131. Omitting Boston, which has peculiar conditions, from both calculations the rate was 111 for the remaining 59 maritime towns and cities against 124 for the remainder of the State. This throws the balance in favor of the seaboard. It should be noted that all the small and sparsely settled towns have low rates in almost regular gradation when compared with more and more populated districts.

Boston has had a noteworthy decrease in its tuberculosis death rate as shown by the following figures representing the rate for the last five years, namely, 271, 283, 254, 176, 182, or a decrease of one-third in five years. There are sixteen small towns having an aggre-

<sup>1</sup> Address to the State Inspectors of Massachusetts, November 3, 1913.

gate population of 5,540, in which there have been no deaths in all of the five years.

The map shows several inland towns with a large death rate owing to the presence of tuberculosis hospitals, asylums, and other institutions. These are marked with an H (not readily seen in the reduced map) and include Rutland, Sharon, Lakeville, Bridgewater, North Reading, Medfield, Westborough, Westfield, Taunton, Danvers, and Monson.

As Mr. Mills says:

Forty years ago the death rate from consumption in Massachusetts was three times as great as it is now; thirteen years ago it had been reduced one-half in the previous forty years; to-day it has been reduced one-half in the past twenty years. There is no other State in the Union, in which records have been kept, where the reduction has been so much. From 1885 to 1909 it was more than twice as great as in England, Scotland, Ireland, The Netherlands, Belgium, Switzerland and Italy. The reduction in Prussia was 90 per cent of that in Massachusetts and that in Austria only 57 per cent. The registration system in Massachusetts is of the highest grade and in no other State or country of the world has such effective work been done and so much accomplished in reducing the death rate from tuberculosis as in that Commonwealth.

#### FOGS ON THE PACIFIC COAST

It is this element of fog which renders so much of the Pacific coast of the United States unsuitable for tuberculous patients. The morning fogs are conspicuous features of the climate and are acknowledged sources of danger to tuberculous cases. They penetrate as far as Los Angeles and Pasadena in the south, some eighteen miles from the coast; they are common in San Francisco, and are carried by ocean atmospheric currents through the Golden Gate, sweeping the bay and up the Sacramento and San Joaquin valleys.

There are portions of the California coast, as for example in the neighborhood of Santa Barbara, where the mountains are near the shore; and beyond the mountains are deserts and necessarily an exceedingly dry atmosphere. The night air from the mountains brings with it a dry Continental quality; the morning breezes bring a more humid air and possibly fog. In such localities fog is quickly scattered by the sun's heat and never penetrates very far inland. A suitable residence for tuberculous patients on the Pacific coast, as every native knows, is not found on the shore line but at some elevation above the sea fairly well up on the hillsides or in well-situated valleys, like the Montecito Valley, where the dryer air of the interior

**STATE BOARD OF HEALTH**  
**MAP OF THE**  
**STATE OF MASSACHUSETTS.**  
**DEATHS FROM CONSUMPTION**

checks the advent of fog and where the early morning hours are as bright and dry as the afternoons.<sup>1</sup>

#### RADIATION FOGS

Fogs are born of the sea and of the land. The sea fog is obviously purer and less injurious than the smoke-laden fog of cities. There are fogs and fogs; "dry" fogs and "wet" fogs; the fogs of the coast and the fogs of mountain valleys and river courses; but rarely of the plains. Radiation fogs are different from sea fogs; in dry weather, on a cold still night when the lowest stratum of air is rapidly cooled by contact with the cold radiating earth, the watery vapor is precipitated as minute globules. The colder the ground or the deeper and colder the water on which fog rests, the more persistent is the fog; but as the sun warms the watery particles and overcomes the heat lost by radiation, the fog lifts and floats upward. It is bound to lift as its specific gravity diminishes. Slopes of hills, especially their southern sides, some hundreds of feet above the lowland or seashore, are thus comparatively free from these fogs and are much drier and warmer than lower places in the neighborhood. Such locations are far preferable to those of lower altitude. (Russell.)

#### FOGS IN THE MOUNTAINS

And here we see how local geographic conditions modify the whole aspect of the question. On the North Atlantic Coast of the United States there are no mountain ranges; one cannot get away from the fogs if he would; while on the Pacific Coast, the mountains and their foot hills are comparatively near and one can be in full view of the seashore and yet be above the fog line.

At Santa Barbara, one of the favorite California resorts for tuberculous patients, fogs occur frequently from May until October, but are comparatively rare at other times. Dr. William H. Flint, who practiced there for thirteen years, says that the fogs creep in from the sea in the late afternoon, in the evening, or in the early morning, disappearing at an uncertain hour the following forenoon. Occasionally fogs will persist all day and for a number of days consecutively. In May and June, 1903, a foggy period continued for seventeen days.<sup>2</sup>

---

<sup>1</sup> See A. G. McAdie: *The Sun as a Fog Producer*, *Monthly Weather Review*, Washington, 1913 (778-779).

<sup>2</sup> *Trans. Amer. Climat. Ass.*, 1904, p. 20.

The late Dr. C. H. Alden, Asst. Surgeon General, U. S. A., who passed his later years, and died of tuberculosis, in Pasadena, California, says:

The climate of Southern California is not a dry one, as some suppose. As this region lies along the coast, and its most frequented portions are nowhere very distant from the water, the climate cannot be dry. The humidity lessens as one goes inland, but is always considerable, except in the uninhabited desert. The fogs which, in the absence of much rain, are a large factor in sustaining vegetation, penetrate many miles from the sea and add to the humidity. *The fact that the humidity is not favorable for pulmonary tuberculosis which is at all advanced is evidently not appreciated as it should be.* [Italics, author's.]

Even as far as Redlands, over fifty miles from the coast, according to General Alden, who lived there for two winters, "fogs come up from the sea during the spring, but they are shorn of most of their moisture." Nevertheless, Redlands, from its comparative dryness, is a favorite place in winter for patients with pulmonary tuberculosis and they no doubt do better there than at Los Angeles, Pasadena, or at resorts directly on the coast. General Alden's conclusion is that while the mild temperatures and continuous sunshine of this region are favorable for the aged and the feeble from many causes, needing an out-door life, the warmth and moisture are unfavorable for cases of pulmonary tuberculosis that are at all advanced.

In June, 1902, the author traveled through the mountains and visited the principal resorts throughout California. The sea air with its frequent accompaniment of fog seemed to him too strong or fresh for tuberculous patients. North of Santa Barbara or Monterey the sea air is certainly cold and harsh during most of the year and, wherever it penetrates, tuberculous patients feel worse. This is particularly true of the neighborhood of San Francisco. From the summit of Mt. Tamalpais, elevation 2,375 feet, on almost any summer afternoon fog can be seen driving in from the Pacific and spreading over San Francisco Bay. As the sun descends the temperature of the air drops, so that saturation is reached. Fog results. Now on the southern California coast the cold, ocean atmospheric currents contain much less actual moisture than the warm, clear air on shore and the resultant mixture will now contain less water than the warm air did before and hence it is claimed with reason that notwithstanding the dripping roofs and wet pavements, there is less absolute moisture in the air than before the fog appeared.

We did not find the California fog either so cold or chilling as we have observed it on the extreme eastern coast of Maine; nor is it so

depressing and relaxing as the heavy misty weather observed in central and western Virginia mountain valleys during the rains of early summer and autumn, certainly not so depressing as the relaxing moisture of the tropics. The California fogs have been likened to the Scotch mist. They never deter the fishermen from curing their fish on their racks along the seashore. Raisins and other fruit are dried in the open fields and residents claim that during the rainiest weather nothing molds or rots. (P. C. Remondino.)

Mr. Ford A. Carpenter, of the U. S. Weather Bureau, has published an interesting book, in which he gives a lucid description of the fogs of the Pacific Coast.<sup>1</sup> He shows that on that coast the maximum fog is reached in San Francisco, with moderately high averages north to the Canadian boundary and decreasing in frequency and duration with the latitude, San Diego having the least on the coast. He says that daylight fogs are practically unknown in San Diego. A "day with fog" is one on which there is one hour or more of fog dense enough to obscure objects one thousand feet distant. At San Diego the hours of greatest frequency were between eleven at night and six in the morning. Mr. Carpenter notes the beneficial effect of California fogs and says that it is impossible to measure accurately the amount of moisture conveyed by fog. There is no doubt that over a region covered by vegetation exposing a natural condensing surface, such as eucalyptus, palm, iceplant, etc., not less than a ton of water to the acre is thus distributed during the prevalence of every dense fog. It also checks evaporation.

"It is not fog in the generally accepted meaning, for this 'light veil' is neither cold nor excessively moisture-laden. Neither is it high, for its altitude is less than a thousand feet. To one who has spent a few weeks of spring, summer or fall in southern California, the picturesque description of the musical Spanish *el velo* is quickly recognized as both expressive and truthful." "*El velo de la luz*": "the veil that hides the light." "*Velo qui cubre la luz del so*": "The veil which shades (covers) the light of the Sun." "*El velo de la mañana*": "*The veil of the morning.*"

There is probably no place on the entire coast line of the United States that offers so many climatic advantages for tuberculous patient as San Diego and its attractive neighbor, Coronado.

It is a mistake to believe that because there is fog, the humidity is necessarily high during its presence. The United States Weather

---

<sup>1</sup>The climate and weather of San Diego, California. San Diego, 1913. See Review in Journ. Royal Meteorological Society, Jan., 1914.

Bureau has taken pains to determine the relative humidity during fogs observed during ten years at Chicago on Lake Michigan. Observations were made on 118 foggy days by Dr. Frankenfield, whose results are given as follows:

Relative humidity 90 per cent (or more) in 75 per cent of days.

Relative humidity 80 to 90 per cent in 13 per cent of days.

Relative humidity below 80 per cent in 12 per cent of days.

The observer noted dense fog on one occasion when the relative humidity was as low as 52 per cent; on another, when it was 58 per cent.

The Pacific coast, as a whole, is much foggier than the Atlantic coast, because the winds on the Atlantic are mostly off-shore and consequently carry less moisture than the westerly on-shore winds of the Pacific.

In the interior of the United States, especially the western half, the average number of foggy days per year is less than ten each year; in the Lake region the number rises to fifteen or twenty per annum. In isolated localities, local conditions increase this number greatly.

At Colorado Springs genuine fogs occur, sometimes very dense and lasting all day, but they are uncommon and scarcely worth mentioning were not their existence so often denied. (Ely.)

In the Adirondack Mountains fogs and mists are not uncommon along the rivers and on the lake shores in the early morning in the summer and autumn. They are examples of the radiation fogs already referred to and, like dew and frost, they are associated with clear weather. The presence of a light fog over an Adirondack lake in the early morning foretells a bright, sunny, warm day.

Fogs are not at all unusual in the Alleghany and Blue Ridge Mountains. They follow river courses and settle in low valleys. The humidity attendant on the melting of snow or during the rains of early summer or autumn is not so readily exchanged for dryer air in the long narrow valleys as at the seaboard. In many localities the high ridges on either side shut out the direct rays of sunlight for several hours; while at the seaboard there are no such natural barriers.

At some of the higher elevations in the Blue Ridge Mountains of Pennsylvania, fog is noted during the summer and autumn. One observer, himself a tuberculous patient, recorded at Mount Pocono, in Monroe County, Pa., elevation 2,000 feet, fifteen days with fog part of the day, usually early morning, and seven with fog all day,

between June 1 and December 1. But this patient adds the significant remark: "However, it seems ridiculous for me to find fault with Mount Pocono when I did so well there. My cough and expectoration decreased considerably; I gained five pounds and grew somewhat stronger."

At Rutland, Massachusetts, the site of the Massachusetts State Sanatorium, there were 24 days with fog for the year ending November 30, 1907. Nevertheless, out of 4,334 cases of pulmonary tuberculosis treated since its opening, 43.39 per cent of cases were arrested or apparently cured, and in addition, 47.38 per cent were improved.<sup>2</sup>

From what has been said, it is, therefore, not surprising that claims are made that there is a noticeable difference in the character of fogs on the New England Coast.<sup>3</sup> Dr. Bowditch has described the fogs on the Maine Coast as sometimes "dry fogs." "The light vapory mist which drives in frequently from the sea has no definite sense of moisture as it strikes the face, and in the midst of it the air frequently feels dry. In the vicinity of Mount Desert, the presence of the mountains has, doubtless, an effect upon the quality of the atmosphere, and would partly account for what is often spoken of—the effect of sea and mountain air combined. Its peculiar dryness, even though on the coast, has been often so marked that I have frequently thought that certain phthisical patients, who need a dry bracing atmosphere, might improve there, although I have never quite dared to recommend it for such cases."

#### SEA AIR FOR SURGICAL TUBERCULOSIS

Halsted, of Baltimore, however, has recorded a favorable result in a case of tuberculous glands of the neck, treated simply by an outdoor life on the Maine coast. The patient was a young lady of seventeen, whose cervical glands were actively inflamed and softened, the overlying skin having rapidly reddened and thinned during a treatment of six hours a day out of doors at a seashore further south. No operation was done, but she was sent to the Maine coast and lived *out-of-doors day and night* for four months. At the end of this period no one could tell, from the appearances, which side had been affected, and Halsted remarked that, to surgeons whose daily bread not long ago was tuberculous glands of the neck, such a

<sup>2</sup> Eleventh Annual Report, 1907.

<sup>3</sup> Vincent Y. Bowditch, Trans. Amer. Climat. Ass., 1897, p. 25.

resolution foretells a revolution in treatment.<sup>1</sup> That revolution is, fortunately, to-day *un fait accompli*.

Some of the European sanatoria of the best grade are in situations not altogether free from fogs and mists. This is true of Falkenstein, elevation 1,378 feet (420 m.), whose atmosphere is a little misty and foggy.

#### AIR OF INLAND SEAS AND LAKES

The region of the Great Lakes lying between the United States and Canada has been studiously avoided in selecting a site for any of the large sanatoria for tuberculosis. It is a matter of common observation that nasal, pharyngeal, and bronchial catarrhs are exceedingly common in adjacent districts. The lake winds are damp and are partly frozen during several months in the year, giving to the surrounding country a harsh climate.

The lower lake region is also the favorite track of storms or cyclonic atmospheric movements which sweep the lakes and the St. Lawrence valley on their way to the seaboard. As these areas of low atmospheric pressure advance they are attended by increasing cloudiness in front and are usually followed by colder air from the Northwest, the fall in temperature being sufficient at times to constitute a cold wave.<sup>2</sup>

The winter storms on the Great Lakes are quite as violent as any on the seacoast, and on Lake Superior and Lake Huron floating ice may be seen in May and sometimes, in Lake Superior, as late as June. Lakes Michigan, Erie and Ontario are more southerly, but their shores are low and the skies are notably cloudy. The author has experience of the cold fogs of Lake Superior in July and August, and was impressed with their penetrating quality. A summer spent on both the northern and southern shores of Lake Superior was wonderfully exhilarating; the air has a purity and stimulus such as one might expect from millions of miles of forest roundabout. But not a single place on that vast shore can be recommended as a residence for a tuberculous patient. The vicissitudes of the weather are such that the approved methods of cure could not well be carried out.

---

<sup>1</sup> Trans. Nat'l Ass. for the Study and Prevention of Tuberculosis, 1906.

<sup>2</sup> To constitute a cold wave, so called, there must be a fall of twenty degrees or more in twenty-four hours, free of diurnal range and extending over an area of at least 50,000 square miles, the temperature somewhere in the area going as low as 36° F.

WALLUM LAKE RHODE ISLAND. PATIENTS OF THE STATE SANATORIUM FOR TUBERCULOSIS  
Courtesy of Dr. Harry Lee Barnes

In the location of the state sanatorium for tuberculous patients in Minnesota, an interior and northerly location was wisely chosen, 150 miles south of Lake Superior, at Lake Pokegama, near the headwaters of the Mississippi.

The Wisconsin State Sanatorium has been located on Lake Nebagamon, thirty miles from Lake Superior.

Such small lakes as Lake Pokegama in Minnesota; the Muskoka Lakes in Ontario, where the Canadian National Sanitarium Association has established two sanatoria for consumptives; and the Saranac Lakes in the Adirondack Mountains, have no such power to modify the qualities of the atmosphere. Whatever influences are attributable to these smaller bodies of water are small, compared with that of the forest and mountains. Undoubtedly a small lake is a desirable feature in connection with a sanatorium, as it provides sources of amusement throughout the year and adds greatly to the beauty of the landscape. The writer spent six summers at Lake Placid in the Adirondack Mountains at an elevation of 1,860 feet. This is somewhat more protected than the Saranac Lakes, St. Regis Lake or Long Lake, and, in his opinion, is quite as well suited as a residence for tuberculous patients as any other locality in the Adirondacks. The State of New York has built its large State Sanatorium at Ray Brook only four miles distant from Lake Placid. The State of Rhode Island has chosen Wallum Lake for its new Sanatorium, views of which are here given.<sup>1</sup>

#### CHAPTER IV. INFLUENCE OF COMPRESSED AND RAREFIED AIR; HIGH AND LOW ATMOSPHERIC PRESSURE; ALTITUDE

No phase of the tuberculosis question has been so vigorously debated as the influence of altitude; no feature of the subject is so far from satisfactory solution. The battles between the Highlanders and the Lowlanders of Scotland seem to have been revived in the attempts to settle this question. Instead of the claymore and battle-axe, we have an array of statistics in serried columns marshalled by the leaders of the opposing forces. This history of the conflict would make as large a record as the Medical and Surgical History of the War of the Rebellion. And the end is not yet in sight.

After trying for years to cure consumption by means of an "equable climate" obtained at home by housing the patient behind double

<sup>1</sup>The large German Sanatorium Grabosee is located on the shores of Lake Grabow.

windows, or by sending him to the islands of the sea, such as Madeira and the West Indies, the medical profession began to be impressed with the good results reported from the Rocky Mountains and the plains of the Western states and territories.

In the rush to the California gold fields in 1849 and in the rapid emigration from Eastern states to Colorado, Utah, California, overland in the "prairie schooner" and on horseback during subsequent years, the Western country became known for wonderful health-giving qualities. It was not long before Colorado became widely heralded as a health resort for consumptives. English physicians sent their patients to Colorado instead of sending them to Australia, Algiers, or to the Riviera and the results obtained were remarkable. The late Dr. S. E. Solly, who practiced in Colorado for thirty-three years, was sent from London on account of the higher altitude and better air of Colorado, and was one of a large number of English residents who have made their home in that state on account of pulmonary tuberculosis.

In 1876, the late Dr. Charles Theodore Williams, of London, published his report to the International Medical Congress and in 1894 issued his work on Aero-Therapeutics, in which are detailed the histories of 202 consumptives who were sent to Colorado at an altitude of 5,000 or 6,000 feet. They represented a residence of 350 years at this elevation and the results were exceedingly satisfactory.

Jourdanet, a French physician practicing in Mexico, published two works, one in 1861 and one in 1875, which undertook to explain the influence of barometric pressure and, incidentally, why, on the plain of Anahuac, 6,000 feet in elevation, there is an entire absence of pulmonary phthisis.<sup>1</sup>

Jourdanet aided the great French physiologist, Paul Bert, in establishing costly apparatus for investigating the physiological action of compressed and rarefied air and Paul Bert's classic work is an accepted authority on this subject. Later studies by Mosso and Marcet<sup>2</sup> should be noted, but it is impossible here to give more than passing notice. They show that a diminution of the barometric pressure increases the respiration rate and the volume of air respired, but if allowances are made for the increase of volume of the air at the lower pressure, the actual volume respired is less. Conversely,

---

<sup>1</sup>D. Jourdanet: *Influence de la Pression de l'Air*, Paris, 1875. Herrera and Lope: *La Vie Sur Hauts Plateaux*, Hodgkins Prize Memoir, 1898.

<sup>2</sup>An American Text-Book of Physiology, Phila., 1901, Vol. 1, p. 434. Angelo Mosso: *Man in the High Alps (Der Mensch auf den Hochalpen)*. Leipsig, 1899), Translation by E. L. Kiesow, 1898.

an increase of pressure lowers the rate and the volume of air respired. The effects of the respiration of rarefied air and compressed air on the circulation and on the composition of the blood are very marked and are of a complex character owing to the additional influences of the abnormal pressure on the peripheral circulation. Not only is the circulation affected but, in the case of residence at high altitudes, the proportion of red blood corpuscles and of hemoglobin is notably increased. This increase in the red blood count at the higher altitudes, while not so great or so permanent as was at first supposed, is an established clinical fact and adds undoubted strength to the claim that altitude *per se* is a characteristic of the favorable climate for tuberculous patients.

#### DIMINISHED ATMOSPHERIC PRESSURE

The influence of diminished atmospheric pressure on the blood has been studied by Paul Bert in 1882,<sup>1</sup> Zuntz,<sup>2</sup> P. Regnard,<sup>3</sup> Viault,<sup>4</sup> Egger,<sup>5</sup> Woolff,<sup>6</sup> Koeppel,<sup>7</sup> Solly,<sup>8</sup> by W. A. Campbell and Gardiner and Hoagland,<sup>9</sup> by L. S. Peters<sup>10</sup> and by F. Laquer.<sup>11</sup> One of the

<sup>1</sup> Paul Bert, *loc. cit.*, studied the blood of animals at La Paz, in Mexico, at an altitude of 12,140 feet (3,700 meters) and found that they had an oxygen-carrying capacity far in excess of that exhibited by the animals on the lower plains.

<sup>2</sup> Zuntz: Experiments on the Pic du Midi, Elevation 9,000 feet. He emphasized the possibility of an altered distribution of corpuscles.

<sup>3</sup> Regnard, P.: *La Cure d'Altitude*, 2eime Ed. Paris, 1898.

<sup>4</sup> Viault: Experiments at Merococha, Peru, elevation 14,275 feet. 1890. He noted that his blood contained 7 to 8 million red corpuscles per cubic millimeter.

<sup>5</sup> Egger: *The Blood Changes in High Mountains*. *Verhandlungen d. xii, Congr. Inner. Med.*, 1893.

<sup>6</sup> Woolff: *Verhandlungen d. xii, Congr. Inner. Med.* 1893, pp. 262-276.

<sup>7</sup> Koeppel, xii. *Congress für Inner. Med.*, 1893; *Arch. Anat. Physiol.*, 1895, pp. 154-184.

<sup>8</sup> S. E. Solly: *Blood Changes Induced by Altitude*. *Trans. American Climatological Association*, 1899, p. 144; also 1900, p. 204.

S. E. Solly, *Therapeutic Gazette*, February, 1896.

<sup>9</sup> Campbell and Hoagland: *Trans. American Climatological Association*, 1901, p. 107.

<sup>10</sup> For the effect of altitude, 6,000 feet, on blood pressure in tuberculous patients, see article by L. S. Peters, Silver City, New Mexico, in *Archives of Internal Medicine*, August, 1908 and October, 1913. The latter report covers 600 cases and shows that altitude tends to raise blood pressure rather than lower it both in consumptives and in normal persons living at high altitudes.

<sup>11</sup> F. Laquer: *Höhenclima und Blutneubildung*, *Deutsches Archiv für klin. Med.* Leipzig, 1913, cx, Nos. 3 and 4, p. 189.

most thorough original studies is by Drs. Ossian, Schaumann and Emil Rosenquist, of Helsingfors, Finland.<sup>1</sup> Turban, also, has made a study of this subject.<sup>2</sup>

Much of the earlier work has been proved incorrect as instrumental and laboratory technic has been improved. Hematologic work has made rapid strides and several important correcting factors have been introduced. Attention has been called to the more rapid evaporation of blood samples at high altitudes where the climate is always dry and errors from this source are considerable.

Not only that, but the human organism itself loses water more readily than at lower levels and so do animals used for experimental purposes. How much value should be given to these corrections we do not know, but there is evidently a revision downwards noticeable in nearly all the later studies of the blood count at high altitudes. Prof. Bürker, of Tübingen, and his colleagues show at best only a comparatively small increase amounting to only four to eleven and a half per cent at an altitude of six thousand feet.<sup>3</sup>

These observers made comparative observations at Tübingen (altitude 1,030 feet or 314 meters), and at the Sanatorium Schatzalp (altitude 6,150 feet or 1,874 meters, about 300 meters above Davos).

Bürker's findings, which appear to result from an exceptionally careful personal investigation with every precaution to avoid experimental error, show that altitude does exert an unquestionable influence on the blood in the direction of an increase in both the number of erythrocytes and the content of hemoglobin. The increase is an absolute one, not merely relative. The red cells increased from 4 to 11.5 per cent, the hemoglobin from 7 to 10 per cent. These figures, it will be noted, are smaller than those usually given for the effect of moderate altitudes, yet they represent substantial and undeniable gains quite in harmony with other previous observations.

The responses of the different persons in Bürker's Alpine expedition varied in degree; but the qualitative examination of the blood established the fact that no hemoglobin derivative other than oxyhemoglobin was concerned in

Die Wirkung auf das Blut, geprüft durch tägliche Erythrozytenzählungen und tägliche qualitative und quantitative Hämoglobinbestimmungen im Blute von vier Versuchspersonen während eines Monats, Ztschr. f. Biol., 1913, Vol. 61, 379.

the increment at altitudes. In agreement with most observers the adjustment of the blood to the new atmospheric conditions in ascending to higher levels occurs promptly; there is a rapid increase in the factors involved at the start followed by a more gradual continuation of the effect; but on returning toward the sea-level the blood does not resume its "low altitude" composition so promptly. There may be a prolonged delay in the adjustment and return to normal figures.<sup>1</sup>

Cohnheim<sup>2</sup> regards evaporation as the cause of the concentration of blood under these conditions and that this is not due to a lack of oxygen. These studies in hematology have an important bearing on the course of tuberculosis at high altitudes, and constitute a very live question at the present day.

Professor Cohnheim and Dr. Weber<sup>3</sup> have recently reported the results of examination of the blood of twenty-three persons who have been engaged for long periods in the operations of the railway ascending the Jungfrau peak in the Alps. Most of them spent considerable portions of their time at altitudes from 2,300 meters (7,546 feet, Eigergletscher Station) upward to 3,450 meters (11,319 feet, Jungfrauoch Station). The importance of these observations lies in the fact that they furnish data regarding persons who have had prolonged experience in the higher altitudes so that the incidents of temporary residence and change of scene may be regarded as equalized or eliminated. They supplement the earlier records from the South American plateaus by results obtained with approved and up-to-date procedures. The new statistics agree in exhibiting values both for red blood-corpuscles and hemoglobin distinctly higher than the "normals" of sea level. Cohnheim maintains that the high figures thus obtained on a large scale from subjects accustomed to live at high atmospheric levels leave no alternative except to assume a new formation of corpuscles under such conditions. Where contrary conclusions have been reached—and there are many such—it is not unlikely that the period of residence was too brief to permit the stimulating effects of altitude to manifest themselves in any conspicuous way.

The renewed assumption of an increased functioning of the hemopoietic organs at high altitudes has further been supported by observations conducted on Monte Rosa in the Alps relating to the regeneration of blood after severe anemias. In the international laboratory built on the Col d'Olen at an altitude of 2,900 meters (9,515 feet) and dedicated to the memory of Angelo Mosso, Laquer<sup>3</sup> has found that dogs deprived by hemorrhage of half their blood-supply regenerate it in about sixteen days. Under precisely comparable experimental conditions twenty-seven days are required at lower levels for the restoration of the same blood loss. Laquer believes that the lower partial pressure of the oxygen is the effective stimulating factor in this more pro-

nounced regeneration so strikingly shown at great heights. How long this latest explanation will withstand the attacks of the increasing number of Alpine physiologists remains to be seen.<sup>1</sup>

The latest observations show that arterial blood contains considerably more oxygen at high altitudes than at sea level. The pulmonary alveoli have a special power of extracting or secreting oxygen and this power is increased in high altitudes, this increase not disappearing until a considerable time after descent to sea level.

W. R. Huggard, of London, an unbiassed and judicial observer, says: "The diminished frequency of tuberculosis with altitude may, I think, be taken as established."<sup>2</sup> Hirsch<sup>3</sup> held the same opinion and based his statement on statistics from various places.

Thirteen years ago, Dr. Solly endeavored to show this statistically and arranged three tables which we append.

TABLE I  
COMPARATIVE RESULTS IN SANATORIA IN HIGH AND LOW CLIMATES  
COMBINED FIRST AND SECOND-STAGE CASES ONLY  
(Taken from Dr. Walters, pp. 52 and 53)

| 1876-1886                          | Altitude  | Number of Cases | Number Benefited | Per Cent    |
|------------------------------------|-----------|-----------------|------------------|-------------|
| LOWLAND CLIMATES                   |           |                 |                  |             |
| Goerbersdorf (Manasse) . . . . .   | 1,840 ft. | 3,615           | 1,294            | 36          |

 " " " " " high " " 86 "

<sup>1</sup>Without Goerbersdorf.

The Goerbersdorf reports up to 1884 are so much lower in the percent of benefited to the others—owing, perhaps, to some different method of estimating results, or, perhaps, to their being taken so many years ago, when the material was worse and the treatment perhaps not as efficient—that probably it would bring out the truth better to omit them.

| Total.....           | 3,186           | 1,841            | Average, 58 |
| HIGHLAND CLIMATES    |                 |                  |             |
| Alps (Davos).....    | 2,027           | 1,551            | 77          |
| Colorado.....        | 571             | 420              | 73          |
| Total.....           | 2,598           | 1,971            | Average, 76 |

The total average of benefited in lowland climates was 57 per cent  
 " " " " " " highland " " 76 per cent

The first table, Table I, deals with the comparative results in sanatoria in high and low climates, first and second stage cases combined being alone taken, and the different variety of forms of improvement being grouped under the head of benefited. Of the lowland sanatoria the lowest elevation above sea-level was 1,840 feet, and the highest 3,300 feet. Of the highland climates the lowest elevation was 4,150 feet, and the highest, 6,000 feet. The total average percentage of benefited in low climates was 71, and in high climates 86.

Table II gives comparative results in open resorts in low and high climates. The total average of benefited in lowland climates was 57 per cent, in highland climates 76 per cent.

TABLE III  
COMPARATIVE RESULTS IN HIGH AND LOW CLIMATES IN OPEN  
AND CLOSED RESORTS

| Sanatoriums                 | Per Cent Benefited | Open Resorts                     |
|-----------------------------|--------------------|----------------------------------|
| LOWLAND CLIMATES            |                    |                                  |
| Hygeia (A. Klebs).....      | 69                 | Average percent of benefited, 58 |
| Goerbersdorf (Brehmer)..... | 76                 |                                  |
| Adirondacks (Trudeau).....  | 77                 |                                  |
| Average.....                | 74                 |                                  |
| HIGHLAND CLIMATES           |                    |                                  |
| Davos (Turban).....         | 84                 | Average percent of benefited, 76 |
| Arosa (Jacobi).....         |                    |                                  |
| Average.....                |                    |                                  |

Table III shows the comparative results in high and low climates in open and closed resorts. The cases, however, could not be obtained in first and second stage cases alone, but only of all stages combined. In lowland climates the closed sanatoria show 74 per cent benefited, and the open resorts 58 per cent benefited. In highland climates the closed sanatoria show 84 per cent benefited and the open resorts 76 per cent, exhibiting the relative superiority of sanatorium over open resort treatment in the two classes of climates, respectively. Doubtless the sanatorium cases were on the whole in better condition upon first coming under treatment than those in the open resorts and, therefore, the superiority of sanatorium treatment over open methods is probably not as great as it appears here; but, nevertheless, even if the material were exactly the same, the sanatoria would show a greater percentage of benefited over the open resorts.

Table III also proves that climate exercises a beneficial influence over patients in closed sanatoria as well as in open resorts. In all stages combined the percentage of benefited in sanatoria in low climates was 74 per cent, while in high climates it was 84 per cent.

In the first and second stage cases combined (see in Table I), the difference in favor of mountain sanatoria is still greater—lowland sanatoria 71 per cent; highland sanatoria 86 per cent.<sup>1</sup>

The following is the classification of the National Association for the Study and Prevention of Tuberculosis adopted in May, 1913. The data given in the table on page 69 are given in terms generally used up to that time.

#### CLASSIFICATION OF SUBSEQUENT OBSERVATIONS

- Apparently Cured: All constitutional symptoms and expectoration with bacilli absent for a period of two years under ordinary conditions of life.
- Arrested: All constitutional symptoms and expectoration with bacilli absent for a period of six months; the physical signs to be those of a healed lesion.
- Apparently Arrested: All constitutional symptoms and expectoration with bacilli absent for a period of three months; the physical signs to be those of a healed lesion.
- Quiescent: Absence of all constitutional symptoms; expectoration and bacilli may or may not be present; physical signs stationary or retrogressive; the foregoing conditions to have existed for at least two months.
- Improved: Constitutional symptoms lessened or entirely absent; physical signs improved or unchanged; cough and expectoration with bacilli usually present.
- Unimproved: All essential symptoms and signs unabated or increased.
- Died.

<sup>1</sup> Dr. S. E. Solly, in the Philadelphia Medical Journal, December 1, 1900.

It is practically impossible to draw accurate conclusions from data furnished by different institutions, under such wide variations as to the character of the patients and varying standards as to what constitutes an apparent cure or arrested disease. A glance at the chart or table shows that good results are obtained at all eleva-

tions. The best results are claimed in incipient cases by the Pottenger (Private) Sanatorium, Monrovia, California, 1,000 feet, and New Mexico Cottage Sanatorium, Silver City, New Mexico, 6,000 feet.

INSOLATION. DIATHERMANCY OF AIR. ALPINE RESORTS

Associated with diminished atmospheric pressure are other important and inseparable atmospheric qualities which contribute largely

to the resultant influence on man's welfare in the higher altitudes. These other qualities have a special influence on pulmonary tuberculosis and should be recognized in estimating the effect on patients of this class.

We have, first, greater insolation. The part played by the earth's atmosphere in arresting the sun's rays is very important and second only to the influence of the atmosphere of the sun itself in arresting the radiation of light and heat from the sun. Slight changes in the sun's atmosphere would speedily alter the terrestrial climate. On the earth's surface at sea level the energy of light of the sun and that of the heat rays are considerably less than at the higher altitudes and recent measurements are of great interest and practical value.

Dr. Julius Hann, the great meteorologist of Vienna, has noted that on the lower plains thirty to forty per cent of the total amount of the sun's heat was absorbed by the earth's atmosphere, whereas at the summit of Mt. Blanc, at 15,730 feet (4,810 meters) elevation, nearly one-half of the absorbing mass of the air is lost and the amount of the sun's heat absorbed was not more than 6 per cent. One can readily understand that when the resistance is removed the light rays are more effective than at sea level. The late Prof. S. P. Langley showed by delicate measurements at this height that the blue end of the spectrum grows to many times its intensity at sea level.<sup>1</sup> This marked diathermancy of the atmosphere goes hand in hand with altitude. The increased facility with which the solar rays are transmitted through an attenuated air accounts for the tan and sunburn so readily acquired on mountain tops and this quality is, in the author's opinion, of value in the prevention and treatment of tuberculosis.

Owing to the increased diathermancy of the atmosphere at elevated stations there is a remarkable difference between the atmospheric temperature in the sun and in the shade. At the higher Alpine resorts for tuberculous patients, such as Davos (5,200 feet), St. Moritz (6,000 feet), Arosa (6,100 feet), and Leysin (4,757 feet), the excessive heat in the sun compared with shade temperatures in winter favors the outdoor life during the "invalid's day." It also, incidentally, impresses all newly arrived visitors as a marvellous climatic feature. At St. Moritz, now a fashionable winter resort, ladies find parasols almost a necessity while friends are skating, and those

---

who indulge in this Alpine pastime revel in summer clothing. Although the climate is a cold one it is characterized by great diurnal ranges of temperature, freedom from dust, winds and fogs, and eminently suitable for the climatic cure.

As the snow lies on the ground at these resorts for from three to five months, sleighing, skating, skiing and tobogganing are popular and some of these sports are allowable in suitable cases of tuberculosis. In March or April the snow melts and the roads become slushy and muddy, so that the air becomes very damp, and patients are accustomed to make temporary visits to lower stations, such as Wiesen (4,760 feet), Seewis (2,985 feet), Thusis (2,448 feet), Gais in Appenzell (2,820 feet), or Ragaz (1,709 feet), returning later to the higher stations.<sup>1</sup>

#### SURGICAL TUBERCULOSIS TREATMENT IN SWITZERLAND

No chapter on high altitude treatment would be complete at the present time without noting the brilliant success of Dr. A. Rollier in the treatment of surgical tuberculosis at Leysin, in the Vaudois Alps, Switzerland. This station has an altitude of about 4,500 feet above sea level. The hospital buildings face the south and are protected by mountain ranges from the cold winds of the north and west.<sup>2</sup> Rollier states that even in midwinter, with snow on the ground, the temperature on the sunny balconies is often as high as 95° to 120° F. Owing to the purity of the atmosphere and the absence of moisture there is little loss of the luminous and caloric radiation of the sun. Rollier established his first hospital for the treatment of tuberculosis of the bones and joints in 1903, but it is only during the last two or three years that his method has attracted so much attention, though Bernard, of Samaden, had practiced it in the pure mountain air of Graubunden in the Engadine; and probably this influenced Rollier to select an elevated site for his hospitals. These are three in number and are located at 1,250, 1,350 and 1,500 meters, or 3,800, 4,100 and 4,500 feet. The exposure of

<sup>2</sup> See description by John Winters Brannan, M. D., *Medical Record*, June 7, 1913. Also Rollier, *Paris Médical*, January 7, 1911, and February, 1913. The author is indebted to Dr. Brannan for his data and to Dr. Rollier for the illustrations and descriptions of his method.

the patient to the sun is the essential feature and after three to ten days of acclimatization indoors he begins with five minute exposures of the feet, five times a day. This is steadily increased as pigmentation appears until finally the entire surface of the body is exposed from sunrise to sunset. The head is, however, protected with white caps and shaded glasses. With the development of the pigmentation the cure progresses until recovery is complete. Dr. Rollier has sent us photographs of a boy who had 32 foci of tuberculosis, even the lungs being involved. This boy was considered cured after fifteen months of treatment. See plate 26.

In another case there were multiple lesions, including a badly disorganized and ankylosed elbow with seven sinuses and a history of three resections of the joint and forearm. This boy also made a good recovery with complete return of function, full flexion and full extension. See plate 27. Dr. Brannan adds that he has seen many such cures at "See Breeze" and has kindly furnished photographs of some of these patients. See plate 16.

According to Rollier the pigmentation is the important element in the cure, inasmuch as it affords to the skin a remarkable resistance, favors the cicatrization of wounds and confers a local immunity to microbic infections. On days when there is no sunshine recourse is had to radiotherapy for the adults and the Bier treatment (local lowering of atmospheric pressure) for the children; at all times, whether the sun shines or not, the skin has its bath of air and light.

Two hundred beds in Rollier's sanatoria are reserved for children.

Dr. Rollier presented to the XVII International Medical Congress at London in 1913, a résumé of his method of heliotherapy and refers to eighteen separate communications to medical literature, in which he and his associates have described the method. Among other things we notice that he reports the number of adults having external tuberculosis treated by him as greater than that of children, 522 to 477. The prognosis for the former is as favorable as for the latter and the duration of treatment is never much longer. In Rollier's paper, referred to, all his cases for the past eleven years are tabulated and out of 1,129 patients, 951 are reported cured. Of the total number only three underwent the operation of resection. These were cases of gonorrhéal arthritis; one was adult of over fifty years. Two cases of tuberculosis of the foot were treated by amputation; both were adults of over sixty years.

Rollier uses fixation by means of plaster, especially in Pott's Disease, but in all cases insists strenuously that the tuberculous joint

FOUR ILLUSTRATIONS OF THE SAME CHILD. HE WAS ADMITTED TO DR. ROLLIER'S SANATORIUM, LEYSIN, AT THE AGE OF FIVE, WITH NUMEROUS TUBERCULOUS FOCI IN THE BONE AND PERIOSTEUM AND ABOUT THE RIGHT EYE. THERE WAS TUBERCULOSIS OF THE ELBOW AND RIGHT FOREARM. THREE PREVIOUS OPERATIONS. SEVEN FISTULOUS OPENINGS IN THE ELBOW; SEVEN IN THE FACE. JOINTS IMMOVABLE; GENERAL CONDITION BAD. THE TWO LOWER VIEWS SHOW THAT AT THE END OF ONE YEAR THE OPEN SORE HAD HEALED. CHILD VIGOROUS.

or other site of the disease must not be covered over by any unremovable apparatus so as to interfere with the full exposure to the sunlight. Rollier's last paper goes very fully into the technic of heliotherapy and the reader is referred to this and to the fully illustrated paper in "Paris Médical," February, 1913, in which there are forty-five remarkable photographs covering the most interesting features of this work. It is at present attracting great attention and American physicians can find in the recent review of Rollier's work by Dr. Henry Dietrich, of Los Angeles, California, an excellent summary of its theory and practice.<sup>1</sup>

Rollier,<sup>2</sup> in his address before the Gesellschaft deutscher Naturforscher and Aerzte in Münster in 1912, says:

It is in surgical tuberculosis that we have seen the best results from heliotherapy, and we have made the treatment of it our life work. As a result of my experience in the use of the light-cure in higher altitudes, based on an experience of nine years, I maintain to-day that the cure of surgical tuberculosis in all its forms, in all stages, as well as at every age of life, can be accomplished.

The closed surgical tuberculosis always heals, if one will only be patient, and above all if one understands how to keep it closed. To transform a closed tuberculosis into an open one means to increase the gravity of the case a hundredfold. A diminution of the vitality of the tissues is the inevitable consequence. . . . To regard a surgical tuberculosis as a local disease which can be cured by local treatment alone is a ruinous error. On the contrary,

it is a general affection which requires general treatment. Of all infectious diseases it is the one in which the individual resistance plays a deciding part. Our first effort, therefore, is directed to improve general conditions and thus to bring about a healing of the local focus by treatment of the entire system. A rational local treatment is necessary as well, provided it is not too one-sided.

In cases of spondylitis, or Pott's disease, the children wear jackets having a large fenestrum cut anteriorly, as the vertebræ in children are not much further removed from the surface of the abdomen than from that of the back. After healing is verified by X-ray a celluloid corset is worn. One or two years are required for the cure. Plate 29 shows a girl thus cured of pronounced Pott's disease with gibbosity, and paraplegia and muscular atrophy. There was complete healing after fifteen months of the solar cure which the illustration well shows.

#### CASES OF HIGH ALTITUDE TREATMENT

As illustrations of the good effect of high altitude treatment, two cases from the practice of the late Dr. Charles Theodore Williams, of London, may be cited. They were both cured at St. Moritz (6,000 feet).

Miss C., aged 18, was first seen by Dr. Williams, July 20, 1887. She had lost a sister from tuberculosis and she had a history of cough and expectoration for five months and wasting and night sweats for two months; total loss of appetite and aspect very pallid. Slight dulness, crepitation in first interspace to the right. Ordered to St. Moritz for the winter. In the spring the patient spent six weeks in Wiesen, elevation 4,760 feet. She entirely lost her cough and expectoration, gained twenty-four pounds in weight and became well bronzed, looking the picture of health. Her chest increased enormously in circumference and measured, on full expiration, five inches more at the level of the second rib than before she left England. She stated that she had burst all her clothes. Careful examination at the end of eleven months, when these later notes were taken, showed great development of the thorax and hyper-resonance everywhere, but no abnormal physical signs. After more than three years in England the chest measurement had somewhat decreased.

Another patient, Miss R., aged 21, was seen in November, 1879, with a history of cough with expectoration, loss of flesh, night sweats, pain in the left chest and evening pyrexia of a month's dura-

FIG. 2. CHILDREN WHO CAME TO DR. ROLLIER VERY SICK NOW INDULGE IN WINTER SPORTS. NO CLOTHING BUT CAPS AND LOIN CLOTHS. NOTE THE MUSCULATURE OF THE CHILDREN FORMERLY SUBJECTS OF COXALGIA, ARTHRITIS, PERITONITIS AND ADENITIS.

tion. Dullness and deficient breath sounds were detected close to the left scapula. After three years of unsuccessful treatment in England, during which time two winters were spent at Hyères, on the Mediterranean, losing ground and growing thinner and showing evidence of commencing disease in the opposite lung, she was sent for the winter to St. Moritz. She returned the following May vigorous and well bronzed, having taken plenty of exercise, skating, walking, and tobogganing. She had lost all cough and had gained much strength. The chest measurement showed an increase of one inch. The whole thorax was found hyper-resonant and no physical signs of consolidation could be detected. After eleven years of residence subsequently in England, she was free from chest symptoms.

In this case, notwithstanding the improvement following two winters spent at Hyères, at sea level, the disease was not arrested and increased the following year. But during one winter's residence at St. Moritz, elevation 6,000 feet (diminished atmospheric pressure and out-door life with winter sports), there was complete arrest of the disease, as the experience of eleven years with absence of physical signs testifies.

There is a wealth of clinical material to show the advantages of high altitude treatment at the well-known European and American resorts. Sir Hermann Weber, of London, and his son, Dr. F. Parkes Weber, have had a long and favorable experience in the treatment of pulmonary tuberculosis in high altitudes and they support Dr. C. T. Williams in a higher estimate of treatment of this disease at high elevations as contrasted with results at the sea level.

Twenty-five years ago Sir Hermann Weber stated that out of 106 tuberculous patients sent to high altitudes, 38 were cured, either permanently or temporarily, 16 were stationary or but slightly improved and 10 deteriorated. More than half of the cases in the first stage were cured.

The American statistics of Drs. Samuel A. Fisk,<sup>1</sup> W. A. Jayne,<sup>2</sup> S. E. Solly,<sup>3</sup> Charles Denison and S. G. Bonney, all of Colorado,

---

are certainly convincing as to the effect of high altitude treatment in the cure of pulmonary tuberculosis.<sup>1</sup>

Solly said in 1888, "Taking the medical profession throughout the world, it is unquestionable that a large majority of those who have made a study of the subject believe that where a change is made, a change to an elevated country is the most likely to benefit a consumptive."

Solly lived for thirty-three years in Colorado after having removed, as a tuberculous invalid, from England. Every one of the physicians mentioned above went to Denver or Colorado Springs as a tuberculous patient, recovered his health there, acquired a reputation and successful practice during fifteen to thirty years of residence and the majority are alive to-day (1913). Those who died succumbed to other affections.

According to Solly, 76 per cent of all patients, good, bad and indifferent, and 89 per cent of those in the first stage that undergo climatic treatment in Colorado are benefited. Would such patients as we have mentioned have derived equal and as lasting benefit at Alpine Stations, such as Davos or St. Moritz, which have a corresponding altitude and an equal barometric pressure? Judging from recorded clinical experience, we believe that they probably would have done equally well. We can never know absolutely. Would they have done equally well at sea-level or at very moderate altitude? None of the physician-patients whose names are quoted would admit it.

Dr. Solly, with his inimitable humor once remarked, "If I were living in London to-day, I'd be dead." In all human probability most, if not all of them, are fair examples of the curative power of the Colorado climate.

Of late there have been dissenting voices, challenging some of the cardinal principles involved in the altitude treatment of tuberculosis. Not only altitude, with its concomitant rarefied atmosphere, but even sunlight itself which lightens the heart of every invalid, have both been denied the value so generally assigned them in tuberculo-

therapy. These discordant notes find utterances among those who have been compelled to treat the poorer class of consumptives in our cities at the seaboard and who have obtained some excellent results. Stress is laid on the beneficial influence, for example, of cold.<sup>1</sup> The fact that patients improve more in winter than in summer is cited to prove that "cold air in itself seems to cure in a manner which nothing else can accomplish. \* \* \* Sunshine is not essential—excellent results may be obtained in climates where the sun is rarely seen. Mere outdoor living seems to be the essential element, and yet there does not seem to be any doubt that quicker results are obtained in the cold season than in the summer."

#### EFFECT OF COLD AIR

There is truth in the proposition that cold air is better for the consumptive than heated air. It is usually purer and is unquestionably more stimulating to the vital forces. Warm sleeping rooms are positively bad because of deficient ventilation. Warmth debilitates and opens the way to bacterial invasion. Hot weather is relaxing, while moderate cold, or greater cold with proper safeguards, acts as a tonic and fortifies the well and sick alike against disease.

The good effect of cold air in tuberculosis is commonly noted by physicians and patients. The following extract from a letter from a tuberculous patient, dated Saranac Lake, New York, February 19, 1908, is interesting:

I have not felt the cold up here this winter as I feared I might, although the mercury has nearly disappeared on one or two memorable nights. 46° below zero is the coldest I have seen it but it was reported 50° below in the village. I am quite used to the cold now as I sit out on the porch all day and have not missed a day yet; but there is one redeeming feature about the cold up here and that is that zero weather does not seem nearly so cold as 20° above in Philadelphia. I really do not begin to feel it until it gets to 20° below, although it is usually too cold to use my hands even in milder weather. J. D.

This patient was 22 years old, had been at Saranac fifteen months and is reported perfectly well and weighs 180 pounds. He is apparently cured. He remains well, Nov., 1913.

<sup>1</sup> Editorial, *American Medicine*, Philadelphia, January 20, 1906.

See A. D. Blackader, M. D.: *The Advantages of a Cold, Dry Climate in the Treatment of Some Forms of Disease* (*N. Y. Med. Journ.*, Aug. 3, 1912).

The minimum temperature at Saranac Lake for 1912 was  $-32^{\circ}$  F. on January 25, and the maximum was  $88^{\circ}$  F. on July 10. The mean temperature was  $40.98^{\circ}$  F. The total precipitation was 43.19 inches, with a total snowfall of 124.24 inches. Clear days, 153; partly cloudy, 77; cloudy, 136.

The extract here reproduced from a letter dated Saranac Lake, July, 1886, is interesting. It was addressed to the author.

The best weather is I think most favorable  
to tubercular patients and the greatest  
improvement takes place from early fall  
to early spring  
Very truly yours  
E. R. Trudeau

The best and clearest statement of seasonal influence on body weight of consumptives that we know of was made by Dr. N. B. Burns, of the North Reading State Sanatorium, Massachusetts. His observations are based on one thousand patients during three years. Fully forty per cent of the cases admitted to this sanatorium were of the far advanced and progressive type. It was noted that August, September and October show that the largest percentage of patients gaining, while the three months immediately preceding show the opposite.

Dr. Burns also charted the aggregate gain in pounds of the male patients treated at North Reading, December, 1911 to 1912, inclusive. There was a rise in January and February, 1912, to 850 pounds for 76 patients which was maintained well through March and April.

J. E. BRUCE

There was a subsequent sharp decline in May, the index dropping 250 points. This fall continued without interruption in June, to culminate July 11, at the low point for 1912.

The conclusion of this study was:

Phthical patients are apt to lose rapidly in weight and general condition in May, June, and the first two weeks in July, which season constitutes an unfavorable and critical period.

Phthical patients make an extraordinary recovery in weight and general condition in the month of August, which is a surprisingly favorable time of the year.

August, September, January and February are the most propitious months for obtaining successful results in treating pulmonary tuberculosis.

Forced feeding in the unfavorable season seems to have availed very little in limited number of cases studied at North Reading.

We have already referred to the beneficial influences of the Arctic summer climate (see pages 39-42), and we attributed much of it to the perpetual sunshine; consequently we cannot agree to the illogical statement that sunshine is not essential. We believe that the "Fireside Cure" has no place in the treatment of tuberculosis and we must admit that whereas only a few years ago the cold air fiend, who slept with windows wide open in the coldest winter, was considered a crank, he now has been proved to be the only sensible one among us.<sup>1</sup>

#### EXPANSION OF THORAX AT HIGH ALTITUDES

Without dwelling further at this time on the effect of cold air compared with warm air on tuberculous disease (see pp. 28, 40, 71), we must note some of the undeniable effects of diminished atmospheric pressure on physical development and especially on the thorax and pulmonary tissue.

One striking change is the expansion of the thorax in various directions and a corresponding increase in the mobility of the thoracic walls. We have previously referred to one case in which the circumference increased five inches during a residence at St. Moritz, elevation 6,100 feet. (See page 74.) Changes of from one to three inches are more commonly noted even at much more moderate elevations. These changes are conveniently recorded by means of

---

<sup>1</sup> American Medicine, *loc. cit.*

the instrument known as the cyrtometer which gives accurate tracings for recording the progress of the patient.<sup>1</sup>

Inasmuch as tuberculous patients in whom the disease is actively progressing show a shrinking of the perimeter *pari passu* with the advance of the disease, and those who are recovering show an increasing circumference, it is a fair inference that the physiologic increase in thoracic measurements due to residence in the higher altitudes is an advantage in the prevention and treatment of pulmonary tuberculosis. Man is not adapted to live permanently at altitudes above 13,000 to 16,000 feet (4,000-5,000 meters), but at somewhat lower elevations as, for instance, at 10,000 feet we have some thriving cities such as Leadville and Cripple Creek in Colorado, and Quito in Equador, elevations 10,000 and 9,350 feet (3,000 and 2,850 meters). The altitude of the permanent habitations in the Ortler Alps is about 5,450 feet (1,640 meters), and that of the highest health stations from 5,000 to 7,000 feet (Arosa). It is a well-known fact that the Indians of the Andes, the Swiss guides, the Tyrolese hunters and other mountain dwellers have a large thorax with correspondingly deep inspiratory power and remarkable endurance.<sup>2</sup> The increased respiration and the quickening of the circulation promote health and vigor in mountain races and comparisons between the highlanders and those in deep and flat valleys are always in favor of the former. All observers have remarked on the immunity from disease, and especially scrofulous and tuberculous disease, characteristic of mountain races, provided they live in the open, avoid overcrowding, have sufficient and suitable food and observe ordinary hygienic methods of life. Failure in this respect provides an opening for tuberculosis which, as we well know, is the scourge of the North American Indian and his relatives in Mexico and South America. Even in Quito, that city of remarkable equability, where it is perpetual spring, tuberculosis has effected an entrance, and enters largely into the mortality lists.<sup>3</sup> In Bogota, South America, in La-Paz, Mexico (elevation 11,000 feet, 3,360 meters) and in other densely populated towns in these countries, the later records show increasing numbers of cases of tuberculosis. This fact, however,

---

<sup>1</sup> See Minor, Charles L.: The Cyrtometer: A Neglected Instrument of Pulmonary Diagnosis and Prognosis (Trans. Amer. Climat. Ass., 1903, p. 221).

<sup>2</sup> "Mexican Indians, though of medium height, have unusually large and wide chests, quite out of proportion to their size." Jourdanet.

<sup>3</sup> Jacoby: Thèse de Paris, 1888. Quoted by Huggard.

should not afford the slightest ground for controverting the general proposition that life at altitudes of from 3,000 to 6,000 feet favors immunity from tuberculosis and the cure of the disease in suitable cases.

#### CHOICE OF CASES FOR HIGH ALTITUDE

The question then arises, what are suitable cases for altitude treatment? What kind of patients may be sent to stations of lower barometric pressure?

In choosing a location, the late Dr. F. I. Knight, of Boston, formulated some opinions based on his long experience.<sup>1</sup> He limited the age of those resorting to altitudes to fifty years. In temperament he preferred the phlegmatic to the nervous, with an irritable heart, frequent pulse, and inability to resist cold; and with the latter we must be careful not to include those who show nervous irritability from *disease*, not temperament, as they are generally benefited in high places. As regards disease, he first considered cases of early infection of the apices of the lungs with little constitutional disturbance, and, although these generally do well under most conditions, yet considerable experience assured him that more recover in high altitudes than elsewhere.

It is best to begin with low altitude in patients with more advanced disease showing some consolidation but no excavation; also when both apices or much of one lung is involved and the pulse and temperature are both over 100.

Hemorrhagic cases, early cases with hemoptysis and without much fever are benefited by high altitudes. Patients with advanced disease, those with cavities or severe hectic symptoms should not be sent to high altitudes. A small, quiet cavity is not a counter-indication; hectic symptoms are counter-indications.

This accords with the latest report from the U. S. Public Health Service Sanatorium at Fort Stanton, New Mexico, altitude 6,231 feet. Dr. F. C. Smith reports 56 deaths from pulmonary hemorrhage in a total of 524 patients since the hospital was opened in 1899. His conclusion is that pulmonary hemorrhage is not more frequent at high altitude than at sea level, but the results are perhaps more often serious, especially in those with impaired circulation.<sup>2</sup>

TUBERCULOSIS SANATORIUM OF THE UNITED STATES PUBLIC HEALTH SERVICE, FORT STANTON, NEW MEXICO. AMBULANT SICK CALL. PATIENTS TAKING BREATHING EXERCISES

Patients in an acute condition should not be sent. Cases of fibroid phthisis, in Dr. Knight's opinion, are not suitable. Convalescents from pneumonia or pleurisy are usually well suited for elevated regions. Advanced cases of tubercular laryngitis, if good local treatment and freedom from dust can be obtained, may do no worse in elevated regions than elsewhere.

In cases complicated by cardiac dilatation we cannot advise altitude; but a cardiac murmur resulting from a long-past attack of endocarditis with no sign of enlargement or deranged circulation should not prevent. Nervous derangements of the heart are usually counter-indications.

The observations made at the United States Public Health Sanatorium at Fort Stanton, New Mexico, by Surgeon F. C. Smith, of the service are commended as a valuable contribution to the Relation of Climate to the Treatment of Pulmonary Tuberculosis. This sanatorium is open to sailors in the merchant marine and they are transferred from the twenty-two marine hospitals on the coasts and rivers to this admirable inland sanatorium. It was found that the results have been nearly three times as good in the cases which left the home stations, *i. e.*, the local marine hospitals, without fever as in those who had a temperature of  $38^{\circ}$  C. ( $100.4^{\circ}$  F.) or more within two weeks of departure. The deaths in those leaving afebrile were to those leaving with fever as 22 to 59; the arrests, as 19 to  $7\frac{1}{2}$ ; the apparent cures, as 10 to 3. Dr. Smith holds that the case that should be sent to a distant climate immediately upon diagnosis is exceptional and he also adds that neglect to make an early diagnosis does not warrant precipitate haste in sending the victim away when it is finally established. The psychologic moment for a climatic change is when there is a comparative quiescence of the lung process under treatment at home, when nutrition is improved and further improvement is slow (Francine). Climatic change, however, must sometimes be made, as we will see later on, when the hoped for stage of quiescence does not occur.

Before allowing patients with pulmonary diseases to go long distances or to make any great change to higher altitudes, some caution should be given. In the first place, patients should not make any physical exertion for two or three weeks after arrival. The air may be stimulating, there may be sights to see and many dangerous invitations given, but it is absolutely necessary that the patient should be adjusted to the new atmospheric conditions. Acclimatization is necessary to comfort and safety. In the old days it was accomplished by the slow ride in the stage-coach over the plains. We cannot go back to the

old methods, and therefore we must exercise greater caution. No febrile case should be sent on these journeys or to any elevated resort. Hemorrhage is not a counter-indication to a change of altitude, and it is not any more liable to occur at five to six thousand feet than at sea-level. However, no advanced case of pulmonary tuberculosis should be sent away. Financial considerations are highly important. Expenses are usually underestimated, and the want of sufficient means, the need to economize as regards the necessities, not to speak of the luxuries, of life, is a dreadful handicap, and should bar out many a case that succumbs for want of the very comforts he had left behind. It would be far better for such patients if they should enter some special hospital or sanitarium for consumption, such as are found in most of our Eastern States.

No one should be sent away without definite and satisfactory knowledge of the place to which he is sent, and without a letter of introduction to some favorably known practitioner containing a statement of the main points in the case.

In matters of climate, as in many other fields, it is the man behind the climate who will help the patient, save him from errors and indiscretions, advise him and direct him as to local surroundings, and enable him so to live that his disease shall be arrested.

Some localities favorable for tuberculous patients have already been mentioned. Taking the country as a whole we naturally look to the elevated, sparsely settled regions of Colorado, New Mexico, Wyoming, Montana, Nevada, Utah, Arizona and California. The slopes of the Rocky Mountains and the Great Basin are justly entitled to first choice, provided always that other safeguards than climate are to had for the protection, the comfort and nutriment of the patient. Texas, especially the central and higher western portion, must be included in this great area. Life in Texas was formerly rather too rough and food and accommodations were too primitive for fastidious people, but now at places like San Antonio and El Paso, these defects have been remedied. The winter climate of Texas is very agreeable, except when the Texas norther descends and holds everything in an icy clasp. However, this is not altogether a disadvantage, if not too severe.

Florida suits some cases of phthisis. The interior of the state is sandy and the winter and spring climate is excellent. The cultivation of orange groves and other agricultural features of the state have given many a patient a profitable occupation that he would never have found elsewhere.

Thomasville, in Georgia, sixteen miles from the Florida line, and Aiken and Camden, in South Carolina, have long had a reputation for the relief of pulmonary affections. Asheville, North Carolina, is more elevated (2,300 feet) and has an excellent "all the year round" climate. Special attention is given to tuberculous patients at this resort, and this is something that cannot be said of all the good places. In Pennsylvania, suitable places are found in the Pocono Mountains, at White Haven, Kane, Cresson, Mont Alto and Hamburg. In New Jersey, there are Lakewood, Brown's Mills, Haddonfield, Vineland, and, for special cases, such as chronic fibroid phthisis, we may advise Atlantic City.

In New York, there are the Adirondacks, especially the vicinity of Saranac; Loomis, in Sullivan County, where there is an excellent sanatorium. In New England, there are institutions at Rutland and Sharon, Massachusetts; Wallum Lake, Rhode Island; Wallingford, Connecticut. But, as we have said before, the choice of a place, whether near home or at a distant point involves all the questions of diagnosis, of temperament, of financial resources, all of which the physician must weigh as conscientiously as though his own life depended on it.

Of late, English physicians have been making more extended use of the higher Alpine resorts. Among these, Davos Platz, altitude 5,200 feet; St. Moritz, 6,000 feet; Arosa, 6,100 feet; and Leysin, 4,712 feet, are usually chosen. Their chief characteristics are an atmosphere of dry, still, cold, rarefied air; absence of fog, few clouds and very little wind. There is, therefore, strong sunlight with a grateful warmth in the sun's rays.

In selecting cases for treatment by change of climate, we must exercise as much discrimination as in applying any other remedial measure. Indeed, more caution should be used, for the patient will pass out of observation and in most cases the advice given involves the most vital consequences.

#### CHAPTER V. INFLUENCE OF INCREASED ATMOSPHERIC PRESSURE; CONDENSED AIR

Celsus, in treating of pulmonary tuberculosis in the first century A. D., advocated a change of climate and to "seek a denser air than one lives in."<sup>1</sup>

A few places in California and in Asia Minor are below sea-level.

---

<sup>1</sup> De Medicina, Paris edition, Delahay, 1855.

But the consequent increased atmospheric pressure in these localities is not in itself worthy of note. Such desolate regions as the Dead Sea, the Mojave Desert, Death Valley, and Salton Lake, California, are entirely unsuited for the tuberculous, and, for obvious reasons, all subterranean pressures are out of the question. Divers and caisson workers become anemic and hence artificial pressures increased beyond the normal at sea level are injurious.

Even the natural variations in atmospheric pressure at any given station may be sufficient to have some appreciable influence, *per se*, on the course of pulmonary tuberculosis. Changes of pressure of 20 mm. (.7874 inches) occasionally take place, but they are comparable to a gradual change of level amounting to only 200 meters (656 feet), and it has been assumed that no appreciable physiologic effects can be attributed to these gradual alterations, at least as far as tubercular diseases are concerned. Hann<sup>1</sup> and Thomas<sup>2</sup> state that in experiments with pneumatic chambers, pressure changes amounting to 300 mm. (11.8 inches) a day have been produced without causing any notable injurious effects upon the sick persons concerned in these experiments.

#### EFFECT OF BAROMETRIC CHANGES ON THE SPIRITS

As the barometric pressure in any given place falls the cloudiness usually increases, the temperature rises, the wind increases, and precipitation is liable to occur; as the pressure rises the skies clear, the temperature falls and the winds shift to the west or northwest. The spirits and general morale of all patients usually improve with a rising barometer unless prolonged wind storms accompany such a change. Whatever improvement accompanies a rising barometer is due to the stimulus of cold or the return of sunshine and dryer air.

Dr. Charles C. Browning, of Los Angeles, has studied the effect of some atmospheric conditions on tuberculous patients.<sup>3</sup> In his first report it appeared that unseasonable or very sudden changes in temperature influenced temperature of patients, while equal or greater changes occurring slowly did not. Of hemorrhages occurring in groups about four times the number occurred when there

was a barometric pressure change exceeding .3 of an inch within twenty-four hours than when the change was less. The hemorrhages appeared to be more frequent if there had been a change in the opposite direction—a sudden fall. The cases observed were all in the advanced stage. The conditions which appear to influence groups of hemorrhages and deaths are barometric pressure, humidity and cloudiness, each in turn appearing to be the most prominent

Chart showing deaths from tuberculosis in the Los Angeles County Hospital and in the city of Los Angeles in 1910. Rainfall, mean monthly temperature and relative humidity are also shown. Courtesy of Dr. C. C. Browning.

index in exerting a limited determining influence. This is shown in the two charts for November and December, 1912. Dr. Browning's paper contains charts for six other months.

Dr. Browning notes the influence of fog and remarks that the "high fog" is regarded by many as one of the most desirable factors of the Southern California climatic condition. It is not fog in the generally accepted meaning, for this "light veil" is neither cold nor excessively moisture laden; neither is it high, for its altitude is less than a thousand feet.

When the barometer is gradually rising and the humidity slowly falling and the sky clear or clearing, patients are pleasant, in some cases jovial and inclined to be optimistic as to the future.

When the barometer is either gradually or rapidly falling and the humidity rising and becoming more oppressive as the hours go by, and the day is foggy with little or no sunshine, the effect on patients is entirely different. They become pessimistic, cross and very irritable. During the so-called "northers," when the barometer falls, then rises rapidly with clear weather and a quick drop in the humidity as from 75 per cent to 20 per cent in twenty-four hours, there is a marked drying of the mucous membrane, causing great discomfort in some and comfort in others.

#### ARTIFICIALLY COMPRESSED AIR

Artificially compressed air has been used by Oertel, Simonoff and Charles Theodore Williams in pulmonary tuberculosis. The first two claimed great improvement resulting from its use; but Williams did not find such favorable effects.<sup>1</sup> In nine cases submitted to the compressed air bath, hemorrhage was brought on in two while in the bath; in four others hemorrhage occurred but could not be distinctly connected with this form of treatment. There was usually some gain in weight and diminished cough and expectoration, and apparently the respiration became freer in the unaffected portions of the lungs. Beyond the opening up or aeration of portions of the lung which had not been brought into play for some time, there seemed to be no special change for the better. Compressed air in Williams's experience did not facilitate the absorption of lung consolidation or infiltration.

At the Brompton Hospital a large wrought iron chamber was constructed about ten feet in diameter by eight feet in height, and accommodated four patients. It had thick glass windows and a closely fitting door. By means of inlet and outlet pipes compressed air was introduced and allowed to escape. The outer air from a pure source was filtered through cotton and pumped into the receiver. The pressure was gradually increased after the patients were inside the tank until it reached ten pounds or two-thirds of an atmosphere above the normal. Half an hour was spent in increasing the pressure, one hour in maintaining it at the highest point required, and half an hour in

---

<sup>1</sup>Charles Theodore Williams: *Compressed Air Bath and Its Uses in the Treatment of Disease*, London; Smith, Elder & Co., 1885, and *Aerotherapeutics*. Macmillan, London, 1894, p. 106.

reducing it; so that two hours were consumed in its application therapeutically.

A practical difficulty was encountered in keeping the compressed air sufficiently cool to be comfortable, owing to the fact that air invariably rises in temperature during compression and cools during rarefaction; so that in warm days ice had to be used about the reservoir.

Von Vivenot, in a careful series of experiments, showed that the influence of compressed air on the respiratory capacity was to permanently raise it. When used for two hours every day it is found to increase daily from 20 ccm. to 30 ccm. above the previous day's record. Von Vivenot took 122 compressed air baths during 143 days and his respiratory capacity was raised from 3051 ccm. to 3794 ccm. and, in compressed air, to 3981 ccm. This increased capacity was reached in three and a half months, after 91 baths and was afterward maintained at practically the same level.<sup>1</sup>

An increase in respiratory capacity has been noted by other observers, but the respiration rate is always lowered and in almost all cases there is a similar lowering of the pulse rate.

#### PNEUMATIC CABINET

These experimental results naturally appealed to phthisiologists and patients were treated at Brompton, as we have mentioned, and in the United States by means of Ketchum's pneumatic cabinet or similar devices. There is no doubt but that the method was given a fair trial, but it has been found wanting. The pneumatic cabinets installed at considerable expense at the Loomis Sanitarium at Liberty, at the Rush Hospital in Philadelphia and at Saranac, are rusting away or consigned to the scrap heap. The simpler and more natural method of outdoor life is found much more safe, rational and effective.<sup>2</sup>

#### ARTIFICIAL HYPEREMIA

We must here refer to an important advance in the treatment of surgical tuberculosis in which artificial changes in the atmospheric pressure play a prominent part. Prof. Bier, of Bonn, first used his famous method in treating tuberculosis of joints; he used the "Stauungsbinde." He also uses cupping glasses of various shapes so that they may be applied to various parts. The rarefaction of the air is accomplished by a rubber ball or a pump, according to the size of the glass. After opening tuberculosis lymphatic glands and tuberculous abscesses in connection with joints, the cupping glasses are applied and the claim is made that this process avoids mixed infections. Tampons and drains, also, are found to be unnecessary.

In treating a member, for instance the hand, Bier uses a glass cylinder provided with a cuff and a rubber band, so that the whole hand is hermetically sealed and by means of the pump the air is partially exhausted. By similar apparatus Prof. Bier, Dr. V. Schmieden, Dr. Willy Meyer, Ewart, and others all over the world have treated successfully cases of surgical tuberculosis so that the method has an established place in tuberculo-therapy.<sup>1</sup>

#### CHAPTER VI. ARTIFICIAL PRESSURE: BREATHING EXERCISES

Radical differences of opinion exist as to the use of artificial variations of pressure, or pneumatic differentiation, in pulmonary tuberculosis and also as to the larger question as to whether the diseased lung should be set at rest or invited to expand.

The respiration of artificially compressed or rarefied air for limited periods, such as half an hour or two hours, has been considered, but this form of pulmonary gymnastics has given way to

<sup>1</sup> August Bier: Hyperämie als Heilmittel, 5th edition. Prof. Bier advises a long continued residence at the seashore in cases of surgical tuberculosis.

more natural methods of accomplishing the results aimed at. The judicious use of exercises has been advocated for centuries and this plan of treatment has passed through most interesting phases, long advocated, then condemned and later revived. Some of the recent advocates of exercise by graduated labor invoke the very latest knowledge of the pathology of tuberculosis in support of this method.

The bad effects of exercise on tuberculosis patients at the well-known climatic stations have been widely commented on and numberless histories of patients going to their death when caution might have saved them are on record. Patients going from the lower elevations to altitudes of five and six thousand feet do not seem to realize at first how necessary are rest and thorough acclimatization for their safety during the earlier weeks or months of treatment. The higher stations are natural gymnasia where diseased lungs may be trained or overtrained; where accidents may happen to the inexperienced and rash, or even to the old time expert if he neglects to exercise proper judgment. No fall from the trapeze is more fatal in its effect than some mountain expedition or other adventure by the tuberculous patient. Dr. Solly was wont to say that nowhere is the invalid fool more quickly punished for his folly than in Colorado.

We are concerned, at present, with exercise as it relates to the breathing habit and the aeration of the diseased lung. Exercises and improved breathing habits can be carried out and acquired at the sea-level or at higher elevations. We believe that at the moderate or higher altitudes breathing exercises are more effective for good and tend more fully to develop the thoracic movements and capacity than at the lower levels (see page 62). Minor has recently reviewed this subject in a paper on the "Use and Abuse of Pulmonary Gymnastics in the Treatment of Tuberculosis" and holds that they are beneficial in properly selected cases. That such measures are abused by those who use them indiscriminately and unintelligently we all know.

#### ATMOSPHERIC COMPRESSION OF LUNG

Fifteen years ago Cornet came out strongly against exercises and others of experience take even more radical ground. The principle of rest has been carried to such an extreme that surgical measures, such as strapping the affected side to insure complete immobilization, have been adopted.<sup>1</sup> The most radical measure was the introduction

---

<sup>1</sup> Charles Denison, Trans. Amer. Climat. Ass., Vol. 21, 1905.

into the pleural cavity of nitrogen gas, or atmospheric air, so as to compress the lung and prevent as nearly as possible all motion. The credit for devising this operation and first performing it, belongs to Forlanini, but it was first practiced in America by Dr. John B. Murphy,<sup>1</sup> of Chicago, and has been repeatedly used by many others in Europe and America, including the late Dr. Henry P. Loomis,<sup>2</sup> Dr. Cleaveland Floyd and Dr. Samuel Robinson, of Boston, Dr. L. Brauer, Prof. T. Beneke, of Hamburg, Dr. H. L. Barnes and Dr. F. T. Fulton, of Rhode Island.

#### ARTIFICIAL PNEUMOTHORAX

Prof. Theodore Beneke, of Hamburg, says<sup>3</sup> that Forlanini conceived the idea of placing the affected lung at rest by artificial pneumothorax as early as 1882; he put it in practice in 1888; Brauer and Ad. Schmidt performed it in 1906. Murphy seems to have developed his operation without any knowledge of Forlanini's work. The operation has been performed in Germany, according to Beneke, by hundreds of physicians on several thousand patients. The operation is meeting with great favor in America.<sup>4</sup>

The clinical observation that the occurrence of pleuritic effusion in tuberculous cases was followed by an arrest of the symptoms of the primary disease if the effusion were left undisturbed; and, further, the unfavorable results which follow tapping in other cases, or when later adopted in cases of quiescent during the presence of the effusion led to this method of artificially producing immobility. Pleuritic effusion is intimately connected with pulmonary tuberculosis in a majority of cases and, if not purulent, should probably be left undisturbed.

Loomis followed Murphy's technique, using a special apparatus for the injection of pure nitrogen gas by means of which from fifty

<sup>4</sup> See article by Dunham and Rockhill, with discussion by C. L. Minor, *Journ. Amer. Med. Ass.*, Sept. 13, 1913.

to two hundred cubic inches were introduced into the pleural cavity on the affected side<sup>1</sup>

The nitrogen gas introduced into the pleural cavity does not remain long without being absorbed, and in order to keep the lung immobilized for six months or more, repeated injections are required. When ordinary atmospheric air gains entrance to the pleural cavity it constitutes the condition known as pneumothorax, and if the pneumothorax becomes closed, the oxygen steadily diminishes and finally disappears, the carbon dioxide decreases and the last element to disappear is the nitrogen. This fact has been determined by chemical analysis by Dory, Bouveret, LeConte, Ewald (Loomis). The respirations are always increased after the injections and the pulse rate is lowered. A notable effect in Dr. Loomis' cases was the absolute control of pulmonary hemorrhage in cases where all other measures failed.

Dr. Loomis' experience in eighteen cases treated by injections of nitrogen gas was uniformly favorable, although not curative. Probably the fact that pulmonary hemorrhage is controlled is the chief value of the method, though gain in weight followed the adoption of this measure in all the cases.

#### SONG CURE

One method of pulmonary exercise lately advocated for tuberculous patients is by singing.<sup>2</sup> Singing invokes correct nasal breathing and a maintenance of the elasticity and proper expansion of the chest. The necessary breathing exercises promote an increased functional activity of all parts of the lungs, including the apices where tuberculosis usually first becomes evident. It is here that expansion is most limited and the prevalent opinion is that this comparative inactivity is a strong factor in the tendency of the disease.

The "song cure" may be suitable in some cases of pulmonary

<sup>2</sup>Drs. Leslie and Horsford, *The Hospital*, London, Jan. 25, 1908.

tuberculosis, but in laryngeal cases it would be counter-indicated. Its practice in pulmonary cases has not been adopted to any very great extent; but it would seem to have some advantages as it does not involve great muscular fatigue.

It is well known that public speakers with pulmonary tuberculosis cannot continue this practice with impunity. Their tendency to attempt to increase their weakening vocal powers by forcing the air outward has a bad influence on the lungs. Bad habits of speaking and lack of training are probably accountable for these bad results. Artistic breathing should be cultivated and all public speaking in crowded and badly ventilated halls should be avoided.<sup>1</sup> Knopf refers to cases of phthisis<sup>1</sup> which had even passed the incipient stage and were cured after following the occupation of street singer or speaker. He cites the case of an English lady who became an evangelist, addressing crowds of people every night in open air meetings and who was actually cured of her tuberculous disease after following this calling for a year.

Our own experience leads us to believe this to be an exceptional result. Having had some experience in treating members of the Salvation Army in various grades of the service, the impression gained was that tubercular disease was quite common among them and that their life of exposure, unhygienic quarters, insufficient food and excessive use of the voice rendered them an easy prey to consumption. The voice is almost always over-strained and hoarse and the open air life the members lead is accompanied by hardships which over-balance any favorable features in their nomadic existence.

Open air singing, properly employed, as in the German Army, is, no doubt, beneficial. This should be encouraged by all military authorities. It relieves the tedium of the march and invigorates the soldier. Barth, of Koslin, has made a thorough study of the effects of singing on the action of the lungs and heart, on diseases of the heart, on the pulmonary circulation, on the blood, the vocal apparatus, the upper air passages, the general health, the development of

the chest, on metabolism and on the activity of the digestive organs, and has come to the conclusion that singing is one of the exercises most conducive to health. (Knopf.)

#### CHAPTER VII. FRESH AIR SCHOOLS FOR THE TUBERCULOUS; VENTILATION

Under the name of "Waldschule" these have recently been established in Germany. The first was opened at Charlottenburg, Berlin, August 1, 1904, and closed its first term October 29th of the same year with 120 scholars. The results of the first year were very encouraging, the average increase in the weight of the children was five pounds, and the Forest School has been regularly opened each year.

The credit of its establishment belongs to the "Vaterländischer Frauenverein" of Charlottenburg. This patriotic association of women selected children either suspected of tuberculosis or with the disease already established for the Forest School. In this way educational facilities are provided for children whose condition renders them unsuitable for the public schools and at the same time avoids the necessity of sending them to sanatoria where there is little or no provision for teaching.

At Charlottenburg they put up so-called "Doecker barracks" or transportable buildings of light construction. There was one school barrack, containing two class-rooms and one teachers' room. The second barrack was used for household purposes. There was also an open "liege-halle" towards the south where the children may remain during bad weather. A light frame structure contains wash rooms and a bath-room with tub and douche. Three schoolmasters and one schoolmistress give instruction. The children were distributed in six classes of about twenty each. This is smaller than in the public schools where there are from forty-five to sixty in a class. The sessions never lasted over two hours continuously.<sup>1</sup>

This school has now grown so as to accommodate 240 children.

A second school is located in M.-Gladbach in the Rheinprovinz. It was opened in 1906 for sixty children between eight and fourteen years of age.

A third one is in Muhlhausen, Reichslande, Elsass-Lothringen, Southwest Germany. It was opened in 1906 and the physician in charge is Dr. Bienstock.

---

<sup>1</sup>For further particulars of this school, see article by Dr. J. Nietner, Tuberculosis, May, 1905.

A fourth is the Forest School in the Victoria Louise Children's Sanatorium at Hohenlychen. It was established August 1, 1903. Pastor Mickley is in charge. These are the pioneer schools and many others have since been established.

The most successful private open air schools in Germany are conducted by Prof. Dr. Gustav Pannwitz, the honorary secretary of the International Association for the Prevention of Tuberculosis. They are situated at Hohenlychen, about two hours by rail from Berlin, near Templin, on the hilly plateau which is called the "Mecklenburgisch—Pommersche—Seenplatte," between the East Sea and Spree Rivers. There are extensive forests of fir, a large lake with an island of 240 acres belonging to the school. It is conducted on the most modern hygienic principles.

An open air school was established at Bostall-Heath, near Woolwich, England, in 1907; in France, at Lyons, Vincennes and Boulogne; in Switzerland, at Lausanne, open from June 5 to September 23, at Zurich and Geneva. The "Rayon de Soleil" at Geneva, is for very young children; so also "Les Oisillons" at Lausanne.

In the United States the first fresh air school for tuberculous children was established in Providence, Rhode Island. Dr. Ellen A. Stone and Dr. Mary S. Packard had a small day camp during the summer of 1907 for children suspected of having tuberculosis. They soon became convinced that a fresh air school ought to be started for the benefit of the tuberculous children of Providence and they asked the help of Dr. Jay Perkins, Chairman of the Providence League for the Suppression of Tuberculosis in getting a single small school, necessarily ungraded, for those children, arranged so as to approximate an out of door school. At the camp which these physicians had been conducting there were about ten children who would soon have to go back to the ordinary schools or else would be at home in close rooms.

In response to this appeal Dr. Perkins enlisted the sympathy of the Superintendent of Schools, Mr. Walter H. Small, and with Judge Rueckert and Dr. Charles V. Chapin, the school committee established the first fresh air public school in America.

A school house not then in use and centrally located was requested for use and granted, and the necessary changes were made. The result was that they had to begin with a room on the second floor the full size of the building, about 40 by 25 feet, with windows on three sides. The brick wall on one-half of the southerly side was removed and windows substituted, these windows extending from near the floor to the ceiling, with hinges at the top and pulleys ar-

LONDON COUNTY COUNCIL'S OPEN AIR SCHOOL AT HORNIMAN PARK, LORDSHIP LANE. REST HOUR

ranged so that the lower end can be raised to the ceiling, thus leaving this half of the room completely open to the south. Each school desk and its accompanying seat is arranged on an individual wooden support so that, while stationary as regards each other, each desk and seat can be moved as desired, and thus any arrangement of seats may be made. The school is an ungraded one (the ages running from 7 to 13 years), and as such limited to 25 pupils. The school hours are from 9 to 11.45 a. m., and from 1.45 to 3.30 p. m., with a recess from 10.15 to 10.45. Towards the end of this recess each pupil is served a cup of hot soup. Each pupil has a sitting-out bag of the standard type and in very cold weather has a hot soapstone in the bottom of the bag. In the end of the room not open to the south a good fire is kept going, thus partially warming the air and keeping that end of the room moderately warm, the pupils' seats all being in the other end.

One interesting feature in connection with the school is that, though these children come from poor homes and there has been an extensive epidemic of "colds" in winter, especially affecting the nose and throat, no child in the school has had even a "cold in the head." On being enrolled, each child is weighed, measured, and the hemoglobin tested. The League furnishes the sitting-out bags and soapstones and some clothing, the city paying all other expenses.

Thus the credit for suggesting the school belongs to Drs. Packard and Stone, but the work was developed and carried on through the efforts of the League. Most of the children for the school are selected in the first instance by the head tuberculosis nurse and secondly by the physicians on the League Committee. All of them are from within walking distance of the school. Dr. Stone is one of the Medical Inspectors of the Public Schools and the other Medical Inspector, Dr. Charles E. Hawkes, was added to the committee.

Providence was the first city in the country to establish special schools for the mentally deficient and the school department is to be highly complimented because of the enthusiasm and energy with which they took up the establishment of a special school for the physically deficient as soon as the matter was presented to them.

This Fresh Air School in Providence was opened on January 27, 1908, with ten pupils, and soon twenty were enrolled. Hot soapstones, sitting-out bags, hot drinks at recess, frequent trips to the stove, breathing exercises, marching, bending movements, and uniform work in singing are prominent features of the pioneer fresh-air school in America.<sup>1</sup>

<sup>1</sup> Ellen A. Stone, M. D., *Journal of the Outdoor Life*, May, 1908.

The instruction of children at the Sea Breeze Hospital for Tuberculous Children at Coney Island is provided by the Board of Public Education of Brooklyn, New York, and the Board deserves credit for thus cooperating with the Sanatorium. Provision is now made in the larger cities for the regular and systematic education out of doors of tuberculous children in the community at large and the success of this movement is attested by the fact that on May 1, 1913, there were 177 open air schools in the United States, five of these are in Rhode Island; thirty in Manhattan; twenty in Brooklyn.

In order to control tuberculosis effectively we shall have to make more determined efforts to reach the school children and even those of earlier years. Tuberculosis is latent in thousands of children in every large city; sooner or later it becomes manifest as vital resistance becomes lowered. A recent view, prevailing in France and Germany, is that all tuberculous infections are made in infancy and childhood, the disease lying latent, from one cause or another, until the individual resistance, weakened by successive colds, pneumonia, grippe or other infections, or exposure to reinfection, finally yields and tuberculosis is actively established. Both laboratory and clinical experience point to a much earlier primary infection than we have been accustomed to believe and hence too much stress cannot be laid on the importance of better ventilated schools and the establishment of more "fresh-air schools" in every city of the country. These should be located near parks, if possible, or at least have extensive play grounds.<sup>1</sup> They should be conducted also for the benefit of children who may be anemic, nervous, and not necessarily tuberculous; and also for apparently healthy children. The best example of the outdoor school for normal children has been opened at Bryn Mawr College, Pennsylvania, as the Phebe Anna Thorne Model School.

Other private schools are advertising open air classrooms, *e. g.*, the Horace Mann School, the Packer Institute of Brooklyn and the Brooklyn High School.

All measures to preserve the purity of air and its freedom from dust should be rigidly enforced in schools. Bad ventilation is the rule except in the most modern school buildings. After two hours the air is depressing and carbonic acid is usually found in excess. The problem of how to deal with dust is a difficult one in schools, owing to the expense of really efficient methods. The floors should not have open crevices and dry sweeping should not be allowed. Sweeping with wet saw dust is probably the most effective, and at the end of each term a thorough bacteriological dust disinfection should be carried out by the Department of Health. Dr. J. H. Lowman, of Cleveland, who has instituted great reforms in the hygiene of the schools of that city, recommends not formaldehyde, but that the walls should be cleaned or painted, the furniture washed and the floors treated with dilute solutions of chloride of lime.

We recognize tuberculosis to be one of the greatest dangers to school children, for at the tenth year the Prussian statistics show that out of 100 boys who die, 9.26 die of tuberculosis, and out of 100 girls, 12.02 die of tuberculosis; hence the importance of all hygienic safeguards against this malady.

Tracheo-bronchial tuberculosis and tuberculosis of the lymphatic system are the forms most commonly encountered and strict medical inspection will reveal large numbers of children for whom fresh air schools or sanatorium schools should be provided. In New York City, out of about one hundred thousand children examined in 1905-1906, over one thousand were found to have pulmonary disease, and in almost every case it was the first intimation to the mother that her child had pulmonary tuberculosis.

Besides the Waldschule of Germany there are specially constructed sanatorium schools in Milan, Italy, and vacation colonies have been established near Geneva, the Swiss Government supplying the teacher while philanthropy supports the schools. In Denmark, where the outing vacations are so thoroughly systematized, the teachers are supplied by the state. The United States show promise of carrying out this enlightened method of dealing with the tuberculous problem. Outdoor schools are conducted successfully in connection with private camps for boys and girls. Many of these are in New Hampshire and Maine, in the vicinity of the Rangeley Lakes, and in Oxford County.

## IMPORTANCE OF VENTILATION

The first desideratum in tuberculo-therapy and in the prevention of tuberculosis is abundant and free ventilation. The dwelling, the bedroom, the workshop, the office, the church, the schoolroom, the theatre, the modern subway are one and all dangerous in proportion, as their atmosphere is composed of dead or rebreathed air. Not only is tuberculosis favored by unhygienic surroundings and vitiated atmosphere in particular, but no other agent, not excepting alcohol and bad food, so surely undermines the constitution and renders it unable to resist disease. Air that has once been breathed, ought not to be breathed again. Out of doors the danger is minimized; indoors we usually breathe and rebreathe the contained air again and again. To some extent, of course, this cannot be avoided, but we should endeavor to reduce it to a minimum. This subject has been recently investigated by Dr. Thomas R. Crowder, who studied by ingenious methods the effect of such factors as change of position, body motion, different types of breathing and different temperatures and, in addition, has determined the conditions that obtain on the sleeping porch and in the open air. Nasal breathing was the type examined, since in mouth breathing there is, under favorable circumstances, little re-inspiration.<sup>1</sup>

The conclusions that may fairly be drawn from Crowder's work are that (1) a person remaining quiet and indoors will immediately rebreathe from 1 to 2 per cent of his own expired air; (2) when lying in bed the percentage is higher, rising to from 4 to 10 per cent, depending on the position assumed while sleeping. "Nor does sleeping in the open insure pure air for breathing. The same influences here produce the same relative results that they do inside. When one buries his head between pillow and bed clothes for the sake of warmth, re-inspiration is inevitable, and it is not necessarily small in amount." In addition, it must be noted that at each inspiration we re-inhale not only some of the air just exhaled, but also the air contained in the nose and larger bronchi—the so-called "dead-space" air. This may amount to one-third of the whole volume in quiet inspiration and not less than one-tenth in deep breathing.

The significance of this study in connection with questions of ventilation is obvious. Since even under the most favorable conditions we cannot avoid drawing back into the lungs some of the air that has just passed out of them, not much importance can be attached to the slight variations in carbon dioxide content which occur in the air of rooms.

---

<sup>1</sup> The Re-inspiration of Expired Air. Archives of Internal Medicine, Chicago, October, 1913, p. 1936. Journ. Amer. Med. Ass., Editorial, Nov. 29, 1913, p. 1986.

THE OPEN AIR CHAPEL, KING EDWARD VII SANATORIUM, MIDHURST, ENGLAND

## OPEN AIR CHAPELS AND THEATRES

It is remarkable how inconsistent we all are in matters of hygiene. Medical men are often among the worst offenders. Their offices are commonly stuffy, their conventions and social gatherings are often held in inadequate halls in which vitiated air, sometimes recking with smoke, is perfectly abominable.

If to do were as easy as to know what 'twere well to do  
Then chapels had been churches and poor men's cottages princes'  
palaces.

We cannot go back to the time of the Druids or worship in groves after the manner of the Greeks, but it seems fitting here to call attention to one chapel that has been specially constructed for out-of-door worship and that is destined to be a model for many a sanatorium at least. This has been constructed for the famous King Edward VII Sanatorium near Midhurst, in Sussex, England. The accompanying illustration of this unique chapel marks a step in advance in sanatorium construction. It is in the Moorish style, shaped like a broad letter V. The double rows of columns of the cloister are on the southerly side, the pulpit and chancel are in the apex and the northerly sides forming the inner walls are provided with arched apertures so that the patients may sit absolutely in the open air but with sufficient protection from the weather at all seasons. In fair weather services are held under the sky in the open space in front of the building between its extended arms. The illustration shows this very beautifully.

Open air theatres were built by the Greeks and Romans and the remains of these structures are among the most interesting of ancient ruins. In Europe the Passion Play at Bayreuth is enacted wholly out of doors, but is entirely apart from our subject except so far as it demonstrates the possibilities of out-of-door representation. The low theatre and concert hall are invariably hot and stuffy and undoubtedly foster tuberculosis by inadequate ventilation. It would be better if we could have some theatres or assembly halls with perfectly free circulation of air.

The Groton School in Connecticut has lately undertaken to build an outdoor gymnasium, so that the boys shall have the advantage of exercise in the open air rather than in an enclosed building. This is the first school we know of to adopt this admirable plan.

## VENTILATION OF DWELLINGS

Ordinary dwellings are terribly deficient as regards ventilation. The country dwellings of the poor are strangely defective in this

respect. It has been said that the reason why the air in rural districts is so pure is that the poor country people have all the bad air shut up in their houses. There is a great deal of truth in this. Doctors are constantly struggling with the strange aversion that the rural population has regarding sufficient air in the bedrooms. As soon as night falls the windows and doors are tightly closed and the kerosene lamp adds to the pollution of the air. It is a common experience to find the doors and windows kept closely shut owing to the deeply rooted fear of catching cold. In European countries the windows of many of the older dwellings were originally intended for light and not for air, and are merely panes of glass built into the wall and not intended to be opened. Others are so badly constructed that the upper sash cannot be lowered and the lower sash is scarcely ever raised more than a few inches.

The children in many country cottages instead of being rosy and robust, as they should be with healthy surroundings, are frequently pale and bloodless on account of this bad air. This deficient ventilation of country houses and the bad food so common, where milk and eggs ought to be so plentiful and good, conspire to give to some country populations a bad start in the earlier years. No better example can be cited than that of the "poor whites" of the Southern United States. Indolence, ignorance, general helplessness and inertia are their characteristics. Their children are pale and gaunt, and their living quarters are horrible beyond description. It is a wonder the death rate among them is not greater than it is.<sup>1</sup>

It seems very strange, but it is a fact, that about seventy years ago a proposition was made to use the Mammoth Cave in Kentucky as a winter resort for invalids. Sixteen consumptives were sent there to gain the reputed benefit from the equable temperature and asserted purity of the air in that cavern. Five of these patients died and the others were injured as a result of the darkness and dampness combined. That such an irrational and cruel experiment should have been tried seems incomprehensible at the present day.<sup>2</sup>

---

<sup>1</sup>The death rate from pulmonary tuberculosis for Virginia during the year ending June 30, 1913, was for whites 98.4, and for colored 256 per 100,000. The state rate was estimated at 148.

## CHAPTER VIII. EXERCISE IN TUBERCULOSIS; GRADUATED LABOR

The Nordrach system of treatment of pulmonary tuberculosis carried out by Dr. Walther and that of his predecessor, Dr. Brehmer, at Goebersdorf, in Silesia, involves much exercise in addition to fresh air and alimentation; the Dettweiler system enjoins rest in the open air with superalimentation. McLean's dictum is: "If the phthisical patient would live, he must work for it."<sup>1</sup> Probably this advice should not be taken too literally, at least by every tuberculous patient; but graduated physical exercise has a very important and useful place in the treatment of most patients. Brehmer advocated hill-climbing, while Walther advises graduated walking exercises, in some cases to the extent of walking twenty miles a day. Whether one practices walking, or hill-climbing or graduated labor, we cannot dissociate from these measures the effect of atmospheric air, in its various qualities, upon the lungs and the accompanying stimulation of the pulmonary and general circulation. Two recent papers by London practitioners are full of such suggestive thoughts on this subject that we call special attention to them. They are considered by some as marking an epoch in the treatment of pulmonary tuberculosis.

At a meeting of the Medical Society of London, January 13, 1908, Dr. Marcus S. Paterson, the Medical Superintendent of the Brompton Hospital Sanatorium, at Frimley, read a paper on "Graduated Labor in Pulmonary Tuberculosis" which was supplemented by another on the "Effect of Exercise on the Opsonic Index of Patients Suffering from Pulmonary Tuberculosis," by Dr. A. C. Inman, Superintendent of the Laboratories, Brompton Hospital.<sup>2</sup>

The patients for whom Paterson instituted graduated labor were selected cases sent from the Brompton Hospital in London to its Sanatorium at Frimley, at an elevation of 380 feet in the country.

He was induced to carry out this plan of treatment after seeing tuberculous patients who did well while working under unfavorable surroundings; but he believed that under careful regulation of labor and with very careful observation of the temperature records, he might safely proceed. The exercises adopted involved all the muscles of the trunk and extremities and this was thought to be better than walking exercises in which the lower limbs were chiefly employed. The use of the upper limbs seemed more likely to favor

---

<sup>1</sup> McLean: Personal Observation in Phthisis Pulmonalis (Journal Amer. Med. Ass., February, 1898).

<sup>2</sup> The Lancet, January 25, 1908.

the expansion of the lungs. It was not forgotten that the common objections to this plan of treatment are, (1) that the disease would become active again under the strain; and (2) that the exertion would tend to produce hemoptysis. Considerable tact and personal influence must have been exerted to get the patients to carry out a plan which involved increasing labor and measures that are generally considered positively harmful.

The first exercise ordered was walking, the distance being gradually increased up to ten miles a day. When a patient had reached this stage he was given a basket in which to carry mould for spreading on the lawns. No case of hemoptysis or of pyrexia occurred among these patients. When they had been on this grade with nothing but beneficial results for from three weeks to a month, they were given boys' spades with which to dig for five minutes followed by an interval of five minutes for a rest. After a few weeks, several of the patients on this work, who were doing well, were allowed to work as hard as possible with their small spades without any intervals for rest. As they had all improved on this labor larger shovels were obtained, and it was found that the patients were able to use them without the occurrence of hemoptysis or a rise of temperature. About this time many of the patients were feeling so well that it became necessary to restrain them from doing too much.

These results in a few cases creates a most favorable sentiment among the other patients so that the system was extended generally, with great care and minute supervision. Harder work was prescribed for patients who could be trusted even to the use of spades, shovels and five pound pick-axes. The patients all expressed the opinion that the work did them good and that the harder they worked the better they felt. Many patients have written to Dr. Paterson to say that they date their improvement from the commencement of the labor, and that they think the hardest work did them the most good. It certainly speaks well for the strict supervision of these patients that no accidents occurred of a serious nature, though several developed fever and, subsequently, pleurisy. One patient was laid up for two months and was much worse at the end of that time, though eventually he did well and returned to work, though the extent of his disease was increased through overexertion.

The suitability of cases for graduated labor rests on a very careful physical examination, importance being laid on the general muscular and physical development. Marked wasting and poor development is, naturally, a bar to this method of treatment. The resisting power

THERAPEUTIC AUTO-INOCULATION ARTIFICIALLY CONTROLLED BY MANUAL LABOR. LOOMIS SANATORIUM, NEW YORK.  
LIGHT GRADE WORK IN THE GARDENS

of a patient with a very limited lesion is an unknown quantity and has to be determined, whereas a patient with a lesion involving four lobes may remain at work for some time and exhibit a good initial resisting power.

Dr. Paterson lays very great stress on the temperature taken in the mouth. If this is or has been  $99^{\circ}$  F. or over during the week preceding admission to the sanatorium, the patient is put to bed after the journey. So long as the temperature remains at  $99^{\circ}$  F. in the case of men or  $99.6^{\circ}$  F. in the case of women, the patient is not allowed up for any purpose. So long as the temperature is unaffected by exertion the patient is gradually allowed up for longer and longer periods. Patients with apparently limited disease, but who are in poor general condition and without fever, are allowed to be up all day, but are not permitted to take further exercise than is entailed by walking to and from the dining hall for their meals. The remainder of the day is spent in resting. As their condition improves they are allowed to walk half a mile a day, and so on, until a distance of six miles a day is reached. The rate of increase in the amount of exercise depends upon such factors as the patient's disposition, weight and appetite.

The grades of work are briefly as follows:

(A 1) Walking from one-half to ten miles daily.

(1) Carrying baskets of mould or other material.

(2) Using a small shovel.

(3) Using a large shovel.

(4) Using a five-pound pick-axe.

(5) Using a pick-axe for six hours a day.

Patients in grades 1, 2, 3, and 4, work four hours a day.

The basket work in which about eight pounds of earth are carried is considered the most important and, as a rule, patients spend far more time in this work than in any other. It brings into use all the muscles.

Work has a wholesome effect on the mind. If the patient is at first sullen and apathetic, the improvement in physical condition quickly begets a lively and cheerful mental attitude, and one that seeks work rather than to shirk it.

During 1905 and 1906 the number of patients discharged from this sanatorium was 164, and they all returned to their previous occupations, whatever they happened to be, and not to light, outdoor work. They were fitted by the line of treatment which we have described for effective wage earning.

We have dwelt quite fully on this innovation in tuberculo-therapy because it gives promise of good, practical results and, further, because it is so radically different from the prevailing methods adopted in most sanatoria. But, the most interesting feature is the explanation which is offered to account for the benefits which has accrued. This explanation is set forth in an elaborate study made by A. C. Inman, M. B., the superintendent of the laboratories of the Brompton Hospital, on the "Effect of Exercise on the Opsonic Index of Patients Suffering from Pulmonary Tuberculosis."<sup>1</sup>

This study of Inman's was prompted and made possible by the brilliant work of Sir Almroth Wright. Wright showed in his Harveyan Lecture in New York, that there are three great agencies by which immunizing responses can be evoked in the organism:

- (1) By the inoculation of bacterial vaccines.
- (2) By artificially induced auto-inoculations.
- (3) By spontaneous auto-inoculations.

Wright had previously elucidated the subject of vaccine therapy by constructing curves from the opsonic indices of patients vaccinated against their infection and in this manner traced a definite train of events which follow upon a single inoculation. The successive phases were termed the negative phase, the positive phase and the phase of maintained high level. Freeman, working in Wright's laboratory, then took up the subject of massage in its effect on gonococcal joints showing that "*Auto-inoculations follow upon all active and passive movements which affect a focus of infection and upon all vascular changes which activate the lymph-stream in such a focus.*"

Wright's dictum was that "where in association with a bacterial invasion of the organism bacteria or bacterial products pass into the general lymph, and blood-stream, intoxication effects and immunizing responses, similar to those which follow upon the inoculation of bacterial vaccines, must inevitably supervene." It is a perfectly logical conclusion, then, that nature cures bacterial infections through such auto-inoculations. Inman set himself to find out what the body is doing of itself and what value extraneous circumstances, such as physical exercise, have in aiding these attempts on the part of the body. Inman's work was conducted on a carefully planned technique, controlled and checked at all points, using forty-three patients in the sanatorium treated by the System of Graduated Labor.

Inman found that in 41 out of 43 cases the opsonic index was at

HEAVY GRADE WORK; ROAD MAKING

some time of the day well above the normal, and what is of even more importance, in no case did the exercise, even though severe, lower the index below the normal line—that is, the auto-inoculation was never so great as to produce a negative phase and, therefore, never in excess.

It was observed during these investigations that in some bloods examined, tuberculo-agglutinins appeared in association with the immune tuberculo-opsonins. This must be taken as another evidence of an immunizing response on the part of the organism. When the difficulties of such a method of treatment and the danger of the weapon employed are taken into consideration it will be readily understood that every now and then, in spite of the most careful supervision, an excessive auto-inoculation must take place. Such an over-dose is readily recognized clinically. A patient doing well on the grade of work prescribed for him and with no abnormality of temperature suddenly complains of feeling tired, of loss of appetite and of headache; and the temperature chart registers an elevation to 99° or 100° F. These are precisely the symptoms which are found during the negative phase after an excessive dose of bacterial vaccine.

Thus we have a new scientific test by which the effect of physical exercise on the blood of patients has been traced. As Inman says :

The opsonic index has shown that the exercise has supplied the stimulus needed to induce artificial auto-inoculation, and that this systematic graduation has regulated this in point of time and amount. This co-operation with the natural efforts of the blood has enabled Dr. Paterson to send his patients back to their accustomed work, however hard it may be. But the investigation has done more than explain a successful mode of treatment. Dr. Paterson agrees with me that with the aid of the opsonic index he can regulate the stimulus with scientific accuracy and obtain his results more certainly and more rapidly. This, of course, involves work in the laboratory. But it also means a more rapid and a more certain discharge of the patient which is the main object of the sanatorium.

Fresh air, exercise, and proper food seem then to constitute the foundation of successful treatment of tuberculosis. The improvement of the general condition of the patient and life in the open air evidently needs to be supplemented by certain exercise so as to produce a series of auto-inoculations and probably the best method yet devised is by the system of graduated labor just described.

All sorts of exercises such as horseback riding, golfing, light dumb-bell exercises and other calisthenics have been practiced for many years in treating tuberculosis; walking exercises have been the feature of some of the German sanatoria referred to; patients sent to the western states and territories almost invariably practiced outdoor exercises, some with great harm and some with benefit. Neither physician nor patient in most instances regulated these exer-

cises intelligently, but groped in the dark, never dreaming of the underlying principles as explained by laboratory studies of Sir Almoth Wright, Paterson, Inman, and others. We trust that further studies and the application of the same method in Europe and America will fix the value of exercise in tuberculosis.

A somewhat similar system of graduated labor has been adopted in the King Edward VII Sanatorium near Midhurst, England. Light work in the gardens and grounds is prescribed in lieu of some of the walking exercise and forms part of the regular treatment. Practical gardening in the grounds and flower beds is utilized. The lightest labor consists of weeding, hoeing and edging paths and borders, gathering seeds, plucking dead flowers, pruning, etc. Somewhat harder exercise consists in wheeling soil to the lawns and spreading it, clearing ground of stones and taking them away in barrows, and in leveling new ground after being broken up. The heaviest work is that of digging and trenching unbroken ground, moving, rolling, etc. Paths through the pine woods have also been constructed. In this particular work the breaking up of the ground with picks and clearing away the roots from neighboring trees was allotted to the first division of patients. The second division cleared away the broken ground and roughly leveled it. The third division finished the leveling of the paths with rakes and tidied up the edges.<sup>1</sup>

Free patients at the King's Sanatorium have made a cinder tennis court; they have cut down and sawed fire wood; they have an open air carpenter shop and an instructor in carpentry, who is himself a patient; they care for the poultry and make the runs for the fowls. In this way patients are constantly occupied.

Although the system of graduated exercises, or labor, adopted at the sanatoria referred to, has attracted wide notice and its principles were there first placed on a highly scientific basis, there were previous attempts to do this in an intelligent and rational manner. Sir Robert Philip, at Edinburgh, over twenty years ago, before the bacteriology of tuberculosis had been so well developed, prescribed practically the same thing as a therapeutic measure of definite dosage. He had had classes of selected patients who came at fixed hours to take regular training with regard to posture and healthy respiratory movement. More especially the young were taught the value of a healthy form of chest, the principles of nose-breathing and full diaphragmatic movement. "In addition to this, measured walks of varying amount and gradient were prescribed exactly

---

<sup>1</sup>Noel Dean Bardswell, *Tuberculosis*, Berlin, May, 1908.

as we prescribe medicines. Thus we had walks radiating from the dispensary round the meadows, walks over the Bruntsfield Links and walks in various directions on the slopes of Arthur's Seat. The patients reported, at successive visits, their experience in carrying out such instructions and notes were made of the effects produced." Here we see the germ of the class method so well developed and practiced by Pratt, of Boston, although he is an apostle of rest rather than labor.

The results in Philip's hands were eminently satisfactory. "The patients did remarkably well and no accident was traced to the adoption of active movement instead of rest. The experience led to a change in my outlook in relation to the meaning of treatment in tuberculosis." Philip came to the conclusion that by the establishment of hospitals or sanatoria for patients in the earlier stages of tuberculosis "we might hope to achieve permanent cures to a degree not dreamt of, by elaboration of the principle of regulated exercises and graded activity of all kinds." These conclusions were justified by the results obtained "in the home treatment undertaken for so many years at the Victoria Dispensary and in the systematized *régime* of work at the Royal Victoria Hospital and the recently opened Farm Colony."

Sir Robert Philip lays great stress on the well-known fact that there is a progressive intoxication in tuberculosis and the toxins produced by the tubercle bacillus appear to exert their vicious influence particularly on the neuromuscular apparatus. The toxin is especially a muscle poison.<sup>1</sup> There is a visible and palpable progressive wasting of the muscles, both of the trunk and the extremities, with advancing flaccidity and increased myotatic irritability. It is an expression of malnutrition, a muscular dystrophy dependent on intoxication. The obvious conclusion is that by the institution of natural movements the physiologic cure of "recreation" is assisted and health gradually returns.

Sir Robert's scheme of physical treatment at the Royal Victoria Hospital is worthy of mention. On admission each patient is placed at complete rest. During this stage, in addition to minute examination of every organ, the patients general condition is carefully observed. According to the estimate which is made the length of the resting period is fixed. Thereafter, in the absence of counter-indication, the patient is gradually advanced through the other stages.

---

<sup>1</sup>R. W. Philip, Trans. International Med. Congress, Washington, 1887, Vol. I, p. 205.

The dose of exercise is increased or diminished as the temperature chart, pulse rate and other indications suggest. A colored badge is given to the patient to denote the stage he has reached.

I. Resting Stage, as noted above. (White Badge.)

II. Stage of Regulated Exercises. (Yellow Badge.) This includes (1) walking  $\frac{1}{4}$  to 5 miles; (a) on the level; (b) on sloping ground. (2) Various respiratory exercises once or twice a day. (3) Other forms of movements to improve carriage of shoulders, head, chest, etc.

III. Stage of Regulated Work. (Pale Blue Badge.)

IIIA. Picking up papers, leaves and other light rubbish on the grounds; knitting; sewing; drawing.

IIIB. (Green Badge.) Emptying waste garden boxes and assisting to carry away rubbish. Carrying light baskets for various garden purposes. Light painting work, wiping shelters; setting tables and laying cloth in patients' dining room; cleaning silver, brasses, taps, etc.

IIIC. (Deep Blue Badge.) Raking, hoeing; mowing; sweeping leaves; light wheel-barrow; heavier painting work; sweeping shelters; scrubbing floors; cleaning knives; assisting in laundry; washing dishes.

IIID. (Red Badge.) Digging; sawing; carrying heavy baskets for various gardening purposes; wheeling and drawing full wheel-barrow and other heavy gardening work. Window cleaning and polishing floors; sweeping and cleaning court yard. Carpentering; joinering; engineering; attending boiler; errands.

An institution providing diversified occupations has a great advantage over one whose patients are restricted to walking exercises and where the women are employed in kitchen work and the men as laboratory orderlies, assistants in the drug rooms, clerks and so on. It is well to vary the walking exercise with manual labor. Patients welcome it and take a great interest in the various occupations they are put to. They acquire confidence in themselves as they see their muscular tone improving and some prospect of resuming useful occupations.

With various modifications suggested by local conditions the system of graduated labor described above is now adopted at various institutions in America; in many cases, however, the economic aspect of the plan of treatment apparently overshadows the therapeutic features; probably the best examples of the method are at the Loomis Sanatorium, New York, Otisville State Sanatorium, New York, The Adirondack Cottage Sanitarium, New York, The North Reading State Sanatorium, Massachusetts, and The Barlow Sanatorium, Los Angeles, California. Dr. Barlow has kindly sent me the following description of the method he has carried out:

This institution is semi-charitable and receives cases in all stages.

You ask me to send you a statement of our use of graduated labor. I will give you the facts as we handle the matter, which is somewhat modified to

TENT HOUSES. BARLOW SANATORIUM, LOS ANGELES, CALIFORNIA

BARLOW SANATORIUM, LOS ANGELES, CALIFORNIA

meet the needs of our institution. It seems to me that every institution must modify this according to the facilities at command. Our working plan is as follows:

All the patients without any fever are kept absolutely quiet for the first two or three weeks, except that they are allowed to go to the dining room for meals. If, during this time, there is no elevation of temperature, no marked acceleration of pulse, and no loss of weight, they are started on exercise, beginning with ten minutes' walking twice a day. If they continue to do well, gain weight, temperature remains normal, and progress of physical signs is favorable, then exercise is increased every two weeks. The amount of exercise is charted for each patient; one copy posted on the bulletin board, and one copy retained by the nurse in charge of the order, to check up the allowance for each patient. Patients who have more than ten minutes' exercise twice a day make their own beds and keep their rooms in order, except the heavy cleaning. After patients have reached an allowance of thirty minutes twice a day, they are assigned to more practical work about the place or grounds. In making these assignments, the patient's physical condition and progress, former, and probably future, occupation are considered. Most of these assignments are changed each month, the effort being to try to increase the work each month. The work done includes the setting of tables in the dining room, removing and washing dishes, work in the diet kitchen, looking after books and pamphlets in the library, cataloguing books, statistical work, stenography and typewriting, carrying mail, light repairs about buildings, care of paths and summer-houses, sprinkling during dry weather, and operating the incinerator. Many patients are assigned to flower beds of their own, or to doing light work in caring for the sanatorium grounds. In carrying out this exercise or labor, careful watch is kept over patients, and if any elevation of temperature, acceleration of pulse, or extension of physical signs are observed, they are put back to rest. The purposes that this exercise and labor seem to serve are, recreation, stimulating the appetite and digestion, building up healthy tissue, inducing healthy sleep, and testing the patients against relapses when they resume their normal way of living after being discharged. We find that patients who accept the occupation cheerfully make better progress mentally and physically than those who resent being assigned to duties.

For patients with an elevation of temperature 99° or over, acceleration of pulse, either loss or no gain in weight, or who do not show improvement in other ways, rest is continued, and exercise or assigned work is deferred.

At the present time (December 11, 1913), there are 43 patients in the sanatorium. Ten are in the infirmary; thirty-three in open-air cottages; of the latter twenty-seven are doing their own work, and twenty-five additional assigned work. Of the six in open air cottages not doing their own work, three are new patients who have been recently admitted and not under observation a sufficient time for report.

#### CHAPTER IX. ACCESSORIES FOR THE FRESH AIR TREATMENT OF TUBERCULOSIS

It would be impossible to carry out the fresh air treatment of tuberculosis without some special facilities or accessories. These vary somewhat in accordance with the plan of treatment, whether singly or collectively; or in cities, forests, or plains. Among these accessories we include: (1) Tents; pavilion tents. (2) Tent houses; shacks, "lean-tos." (3) Disused trolley cars. (4) Balconies or leigeterrasse for day use. (5) Day camps. (6) Sleeping porches or balconies. (7) Wooden pavilions. (8) Glass pavilions. (9) Hospital roof wards. (10) Detached Cottages. (11) Sleeping canopies.

*Tents.*—Tents have the advantage of low cost, portability, and the fact that they are adapted for almost any locality, whether in the city, the forest, or the plains. In the city a tent for the use of a tuberculous patient usually attracts too much notice and unfavorable comment unless placed in a rural district. It is possible, however, to erect tents in the heart of a great city, hundreds of feet above the ground where an abundance of pure air and sunlight are obtained. The modern hotel or office building can furnish a far better site, in these particulars, than many rural districts. The author is not aware of any extensive use of tall buildings for the treatment of pulmonary tuberculosis, but it would seem to be an entirely feasible proposition.

TENTS FOR TUBERCULOUS PATIENTS, SUNNYREST, WHITE HAVEN, PENNA.

ESTES PARK, COLORADO. CHEAP BUT COMFORTABLE TENT FOR SUMMER USE  
Courtesy of Dr. S. G. Bonney

Anyone who will read the interesting story by Van Tassel Sutphen entitled "The Negative Pole,"<sup>1</sup> will find the history of an interesting case of pulmonary tuberculosis cured by residence of eighteen months on the top of a modern "skyscraper." The patient had been advised to remove to Arizona, but circumstances made this advice impossible to follow; as an alternative measure he isolated himself almost entirely from the world in the midst of a metropolis, and was rewarded by a complete cure. The imaginative author of this original story assigns to the patient a much more difficult rôle than need be assumed by anyone who may follow the general line of treatment and perhaps we may hear of many who may be encouraged to carry out the plan suggested.

In the forest during the warmer season tents are almost indispensable. A substantial tent properly erected, protected with a "fly" and with a surrounding trench to provide for excessive rainfall, can be made a comfortable and healthful habitation during a large part of the year.

The ventilation of tents, and their heating in cold weather, have received a great deal of study, and as they are perfected in these respects their suitability for a continuous residence throughout the year has been proved. Tents can be made storm proof and almost as comfortable in stormy weather as an ordinary building. On Blackwell's Island and on Ward's Island, New York City, tents are in constant use, with astonishing success for tuberculous patients.

At the Manhattan State Hospital East, for the insane, Ward's Island, New York City, the late Dr. A. E. Macdonald instituted, in 1901, a tent colony for the tuberculous patients.

This experiment resulted most favorably and led to the extension of the outdoor treatment to other classes of the insane besides the consumptives. For thirteen years the consumptive insane on Ward's Island have been treated in tents and pavilions. Tuberculous infection has been removed from the wards and 11.39 per cent of patients are reported to have had their tubercular disease arrested. They almost invariably gained flesh; one is reported to have gained 79.5 lbs. (Eighth Annual Report, Manhattan State Hosp., New York.) In the Eighth Annual Report the following comment is made: "In our experience the winter months have proven to be the most favorable for these patients, despite popular opinion to the contrary, and likewise it is seen that the summer month of July was in a decided manner proven to be the least favorable of the year."

---

<sup>1</sup>Harper's Magazine, July, 1908.

The accompanying illustrations show fully the initial stage of this experiment in a portion of New York City having many natural beauties. But in the course of time it was apparently realized that the same results might be obtained with other structures of a more permanent character and I am informed by Dr. William Mabon, the superintendent and medical director, that the tents have been replaced by wooden and glass camps. The reason for this change is that the tents were found to be very close and unsatisfactory in wet weather, whereas the wooden camps can be opened and ventilated under all conditions of weather.

*Pavilion Tents.*—On Blackwell's Island, New York, the Metropolitan Hospital makes use of twelve pavilion tents with a capacity for 142 patients. Steam pipes are arranged in a double circuit and in some cases stoves render these pavilion tents comfortable in winter and were preferred by the majority of the patients, in the coldest weather, to the ordinary quarters in the main building of the hospital. These pavilion tents were devised by Dr. A. M. Holmes, of Denver.

The tent devised by Dr. Charles Fox Gardiner, of Colorado Springs, is largely used in western sanatoria and has some notable advantages. It is of conical shape, like the Sibley army tent, with a ventilator at the apex of the cone which may be opened or shut. The board floor has an air space beneath and air inlets opening at the floor between the interior wainscoting and the tent wall supplying air at the height of three or four feet above the floor. This is an improvement over the method of allowing air to enter at the floor. These inlets are controlled by hinged lids. This tent avoids the use of a center pole, pegs, or guy-ropes, as it is supported by two-by-four-inch timbers reinforced by angle irons and plates. This tent costs from \$90 to \$100 and is thoroughly practical. It is not unlike the Nordrach tent. (See plate 55.)

The tent devised by Dr. H. L. Ulrich, of Minneapolis, is simpler and less expensive. It consists of a wall tent with ridge pole for the tent, and another 12 inches clear above it for the "fly." There are ventilating openings on either side of the tent ridge. The tent and "fly" are secured by guy-ropes and pegs and all four sides may be rolled up and lowered as required. A stove may be used in cold weather. A tent 10 by 12 feet costs \$22.50.

Other excellent tents have been devised by Prof. Irving Fisher, of New Haven, Dr. Mary Lapham, of Highland, N. C.,<sup>1</sup> and Dr. James A. Hart, of Geneva, New York, and Colorado Springs.

The evolution of the tent and open air shelter into the tent house, shack, and cottage, is an interesting feature of the open air treatment of tuberculosis.

"*Lean-to*."—The open air shelter and "lean-to" are somewhat alike. The latter has been long used by sportsmen and others in our northern forests, and has been greatly amplified for sanatorium purposes. The roof of the "lean-to" slopes directly back from its front or there may be a ridge placed close to the front or southerly side of the structure. The roof slopes well toward the back, but is short in front and allows free access of air and light. Canvass or screens are arranged to hang in front as a protection from wind or rain, and to insure privacy. For a full description of a "lean-to" the reader is referred to Dr. H. M. King's description with plans in "Some Methods of Housing," Charity Organization Society, New York.

Excellent "lean-tos" or open air shelters are in use all the year at the Royal Victoria Hospital, Edinburgh, Scotland, as seen in the illustration kindly supplied by Sir Robert Philip. (See plate 56.)

Pavilion tents are amplifications of the tent cottage, and are adapted for ten or twelve beds. As described by Mr. Homer Folks, they are sixteen by thirty-two feet long; the walls are eight feet high; the roof is fifteen feet high at the ridge and the floor of the tent is sixteen inches above the ground with free circulation of air underneath.

*Tent Houses* adapted for use in the New England and Middle States are naturally different from those in use in New Mexico and Arizona, where rain and snow are uncommon. The accompanying illustrations show a row of six tent houses and a single tent house at the U. S. Public Health Sanatorium at Fort Stanton, New Mexico, for consumptive sailors, under the care of the United States Public Health Service. The roof has a slight incline and the sides are arranged to give free ventilation as well as shelter when required.

*Trolley Cars*.—Superannuated and disused trolley cars were first used for tuberculosis patients by Dr. W. H. Peters, of Providence, Rhode Island, at the Pine Ridge Camp near that city. With slight alterations and at very little expense these cars may serve a useful purpose in connection with the outdoor treatment of tuberculosis at all seasons. Once located on a convenient site they have many advantages over the ordinary shack, affording a maximum of light and air and good protection against storms with their adjustable windows and doors. The author visited Pine Ridge Camp and can testify to

their efficiency; the camp itself was discontinued after the erection of the fine State Sanatorium for tuberculosis at Wallum Lake. Trolley cars were also used at the Camp Auxiliary, Montefiore Home, Bedford, New York. (See plates 67 and 68.)

*The Balcony, or Liege-terrasse* as it is known in Germany, is a necessary adjunct of any sanatorium for tuberculosis. Plate 71 shows a covered or partly sheltered balcony in use at a large private sanatorium in St. Blasien in the Black Forest, Germany. Plate 89 shows an open or uncovered balcony at the Sharon Sanatorium, Massachusetts. In June, 1908, the author visited the latter sanatorium with the Medical Director, Dr. Vincent Y. Bowditch, and can bear witness to the excellent arrangements for the outdoor treatment of tuberculosis carried out at this institution.

The records, now extending over 22 years, show that about 50 per cent of all cases, and 72 per cent of all incipient cases have been arrested or cured.<sup>1</sup> Of the 160 arrested cases treated between 1891 and 1906, 133 or 83 per cent were still living and well in 1908, most of them house-keepers and wage earners; in addition, 3.7 per cent were doing well at last accounts, but were not recently heard from.

We have given the particulars of these cases treated at Sharon Sanatorium because the results are remarkably good being obtained at an elevation of 250 feet above sea level, about 15 miles from Massachusetts Bay, and about 20 miles from Boston. Sharon is near enough to the ocean to be affected by the sea breeze during the hot weather.

*Day Camps; Walderholungstatten.*—The daily care of consumptives at a day camp for the outpatients of a general hospital had its origin about the same time in both Boston and Berlin. It was proposed by Dr. A. K. Stone and Dr. E. P. Joslin in 1905 in Boston, and provision was made at the Mattapan Day Camps and at the House of the Good Samaritan for ambulatory patients. Plates 72-74 show how this is carried out. In July, 1908, fifty consumptives too ill to be benefited by treatment at the Massachusetts General Hospital were transferred to the new home of the Boston Consumptives' Hospital on the Conness estate, Mattapan, and entered on treatment which it was hoped would culminate in their improvement to an extent that should warrant their entrance into the state institution. They went to the camp in the morning and returned to their homes

at night. Those given preference in treatment were patients whose dependents, circumstances, and health most demanded it. The new hospital and its location are picturesque as well as healthful, and patients are able to remain throughout the winter. The main building is 125 feet long and contains dining-room, kitchen, examination and rest rooms, and has a spacious veranda facing the south. It is designed to accommodate 150 patients, in the two pavilions, two cottages, and children's building. The Day Camp has proved to be a great success.

Day camps, when properly conducted, have an immense value on educational lines. In addition they remove for a time the sources of infection from the community and from the homes. These patients cannot always go to a sanatorium but in this way receive proper care during a large part of the day and may eventually avoid the necessity of going to a sanatorium; others who need sanatorium care are provided for, pending admission; and after discharge from the sanatorium the camp helps to complete the cure. Dr. Otis does not believe that these camps are destined to become a permanent therapeutic measure in conducting the cure.

The best location for day camps is in the forest. In Germany they are known as *Walderholungstätte* and there are over eighty of them scattered throughout the Empire. Those who are only slightly affected with tuberculosis, or are convalescent from it, pass the day in camp and return at night to their homes. The accompanying illustration (pl. 76) shows these camps for adults and children at *Kuhfelde*, Germany. These forest convalescent homes are greatly favored by the German insurance societies and sick lodges. Their benefits are extended to the children of patients.

Germany must be given credit for making the greatest discoveries and for instituting the most rational methods of treatment in connection with tuberculosis. The most thorough measures are adopted by the Imperial Government, the industrial insurance companies and by the medical profession of Germany.

According to the business report of the German Central Committee for the campaign against tuberculosis, there were in Germany in 1908 99 popular sanatoria for adults affected with disease of the lungs. These have 10,539 beds, 6,500 for men and 4,039 for women; in addition there are 36 private sanatoria with 2,175 beds, so that in all, 12,714 beds for adult tuberculosis patients are available. For children with pronounced tuberculosis there are 18 sanatoria with 875 beds; besides there are 73 institutions, with 6,348 beds, in which

are received only "scrofulous" children and those who are threatened with tuberculosis. During the last five years these facilities have been greatly increased; 31,022 insured persons were treated in the sanatoria during a total of 2,312,850 days of care, at a cost of 11,483,033 marks (\$2,755,928). On an average, each person treated received 75 days of care at a cost of 370.16 marks (\$88.84) or 4.96 marks (\$1.19) per person for each day of care.

*Night Camps.*—These afford open air conditions of sleeping, either for patients with arrested tuberculosis who pursue their occupation by day in the nearby city, or with disease still unarrested but who are able, or from necessity are compelled to work by day.<sup>1</sup>

*Sleeping porches and balconies.*—Sleeping out of doors requires special arrangements which are not usually found in cities. The ordinary dwelling, apartment house, or tenement has no provision for this innovation in tuberculo-therapy. Suburban and country houses or those in the less crowded cities are better adapted for the conversion of an upper porch or balcony into a sleeping apartment. In Denver, for instance, the practice is common enough to excite little comment. Detached houses are usually easily fitted with the necessary screened enclosures.<sup>2</sup>

*Pavilions* are more substantial and permanent than the forms of shelter previously referred to. Where large numbers of patients must be cared for at a minimum of expense the pavilion system has distinct advantages, especially for night use. At the Metropolitan Hospital, Blackwell's Island, New York City, about one-third of all consumptives under hospital care in New York are there provided for in the tent pavilions referred to on page 123; these tent pavilions cost about \$12.00 per bed or \$144.00 for a tent pavilion with a capacity of 12 beds.

At the Manhattan State Hospital for the Insane, Ward's Island, New York, more substantial and permanent pavilions have been constructed of wood and glass and have displaced the cloth tents. These pavilions are heated by steam, lighted by electricity, and have removable glass sides permitting a free circulation of air and light all the time. Their per capita cost is about \$100.

In addition, there are camps for both the men and the women with a total capacity of 175 patients. In summer some canvas tents

are used. The accompanying photograph (pl. 83), kindly furnished by Dr. Wm. Mabon, the superintendent, shows the character of the pavilion.

In the Royal Victoria Hospital for Consumptives, Edinburgh, Scotland, still more substantial and expensive pavilions are in use as seen from the illustrations (pl. 84) kindly furnished by Dr. R. W. Philip.

*Roof Gardens.*—At the Philadelphia Hospital the first attempt to segregate tuberculous patients for the fresh air cure was by means of a roof garden ward. This was a vast improvement over the previous method of indoor confinement and was greatly appreciated by the patients. The roof garden ward was in use winter and summer, but later gave way to the six glass pavilions erected at an expense of over \$112,000.

Each pavilion is intended to accommodate eighteen patients, usually in an advanced stage of tuberculosis. Each is separate in itself with walls and roof of glass and only sufficient metal work to give proper support. The floors are of cement so as to be as smooth and non-absorbent as possible. Including the porches, which are also enclosed in glass, each pavilion measures 39 by 70 feet. The glass is arranged in frames in both walls and porches and by means of automatic devices one side of the building or all three sides may be thrown open. Screens or shades are arranged to prevent too much access of the sun. The system of ventilation and heating is considered ample.

*Detached Cottages.*—At the Nordrach Ranch Sanatorium, three miles from Colorado Springs, independent cottages resembling tents are used. These are economical and insure privacy and sufficient protection. The system is adopted from that in use in Nordrach, Germany.

The highest development of housing for the tuberculous patient is undoubtedly the independent cottage. It is necessarily expensive, but the patient fortunate enough to be its inmate has a maximum of comfort and at the same time is in the enjoyment of the best atmospheric conditions night and day. At the Loomis Sanatorium where the snow lies on the ground more than four months in the year, and at Saranac Lake, in the Adirondack Mountains, where the winters are even longer and more severe, the independent cottage is a distinctive feature.

*Sleeping Canopies.*—Detachable windows may be applied to tents, pavilions, or ordinary dwellings, so as to allow patients to breathe

by day and night the outer air uncontaminated by others occupying the same room or dwelling. Devices suitable for any window may be obtained. It is thus possible in a hospital ward to have half a dozen patients breathe the outer air while the ward is kept warm. The tent can come over the end of the regular hospital bed so that patients sleeping in wards where miscellaneous cases are received, may nevertheless have the full benefit of the outer air. By means of thick celluloid the patient may be readily seen. The celluloid window may be raised to give the patient drink and nourishment.

Plate 93 shows the Walsh Window Tent applied to the window of an ordinary dwelling.<sup>1</sup>

#### CHAPTER X. CONCLUSIONS.

There are some people, especially those of a skeptical or combative tendency, who refuse to admit that climate plays any important rôle in the cure of tuberculosis. One of these who was formerly in charge of a widely known institution for the study and treatment of tuberculosis has said: "I desire to go on record as believing that there is no therapeutic value in climate." This same physician probably owes his life to the fact that thirty-five years or more ago he left the city and removed to the mountains of Pennsylvania for the relief of a pulmonary disease and recovered. Such an attitude is a study for the psychologists and would hardly seem deserving of serious attention, except that we hear such statements as this: "If a case of consumption cannot be cured in its home climate it cannot be cured anywhere."

I think there is no doubt that if any of us were told that he is in the incipient stage of tuberculosis he would immediately take steps to familiarize himself with the line of treatment which would, before much time had elapsed, involve leaving Boston, New York, Philadelphia, or Chicago, as the case might be, and so live as to enjoy what air and sunshine and other atmospheric features might afford.

One reason why home climates, if such a term may be permissible, have grown in favor is that it has been found necessary to establish a large number of State sanatoria, or at least to seek aid for private sanatoria from some of our State legislatures. It is a matter of expediency to have such sanatoria and legislators must be convinced that good results or, if necessary, the best results, can be obtained close at hand. We are all heartily in favor of such institu-

---

<sup>1</sup> For the history of this tent see Knopf and McLaughlin, *N. Y. Med. Journ.*, 1905, Vol. 81, 425.

tions whether or not we should wish to stake our chances of recovery in any of them.

Of course we do not claim that there is any specific climate for tuberculosis and the long search for such climate, a search lasting for nearly two thousand years, is apparently at an end.

Now what is there left to us, and what do we understand by a climatic change?

We all know that the New England climate is changeable, that is, the meteorological conditions are constantly varying just as they also vary in the Mississippi Valley and along the Atlantic seaboard. But the New England climate is peculiarly unstable and, as Charles Dudley Warner has said, "New England is the battle-ground of the weather."

We have a change of climate when we leave the hot city in summer and go a few miles to the shore. We have floating hospitals so that this climatic change may stimulate a sick child to recovery. A so-called "home-climate" may work a cure or aid in a cure because we leave the climate of our homes, often too dry with furnace heat, too poorly ventilated, too damp from lack of sun, and remove to more hygienic dwellings in the same locality where sun and air and cleanliness abound.

But, to take up the principal question at issue, the first thing usually asked is whether one should go to the Adirondacks, Colorado, New Mexico, Arizona, California, or elsewhere, in order to get what is so frequently claimed to be the greatest climatic advantages. No one who has visited these localities can fail to be impressed with the living examples of recovery from tuberculosis. Denver, Colorado Springs, and innumerable towns in southern California abound in doctors who have practically recovered from this disease and are earning a living that is the envy of their eastern confrères.

Would they have recovered in their eastern homes? Almost to a man they answer "No." I have never heard of an exception. But the case is hard to prove from such *ex parte* evidence. However, it is interesting to note Dr. H. B. Dunham's conclusion. He stated in 1904, after visiting discharged Massachusetts State Sanatorium patients in the west, and after comparing Massachusetts Sanatorium statistics with those of the U. S. Army Sanatorium at Fort Bayard, New Mexico, that "the results corroborate our beliefs in the efficacy of residence in dry climates, but with a smaller margin in its favor than was anticipated." The proportion of people adapted for treatment in these extremes of climate must be more equal than

thought possible by climatologists generally. That is to say, a small majority of the patients at Rutland, Mass., would probably do better at Fort Bayard, New Mexico, and a large minority might do better at Rutland. But no one can say positively, in any given case, what would have been the outcome had he chosen differently.

We need not discuss the bearing of what to do for the poor or what to do for the rich, or the question of food, or the physician's management; these are important and may govern the choice, but what we want is an answer to the abstract question of the influence of climate.

We believe that climate may be *utilized as an adjuvant* of great value for carrying out the hygienic, dietetic treatment of all forms of tuberculosis and of many other diseases. There are some elements of climate that have a more positive influence in hastening cure than others. The first place must be assigned to an abundance of air, which is as nearly as possible bacteriologically and chemically pure. It goes without saying that city air is polluted by smoke and dust and all dwellings, whether in the city or the country, are far below the standard of purity desirable. Only on the sea or at the highest elevations do we find air really pure, but we can approximate it by living out of doors. There is a climate of the city, a suburban climate, a climate of the country, woods, and plains, all differing as regards purity of air. We are all probably agreed on this point.

Next comes the subject of sunshine. We admit that good results are obtained in cloudy regions as, for instance, in the Adirondacks and at Rutland; but there is at least no objection to sunshine, and I believe that the moral effect of bright sunny days and plenty of them is very great. Invalids always welcome the sun. We can protect ourselves from too much sun if need be, and I, for one, believe that sunlight does a vast amount of good and sunny regions are much to be preferred, other things being equal. That is the great asset of our western plains and mountains; and it is a real asset that counts. Of course there are exceptions. Tastes differ. Dr. Solly used to relate the story of one of his countrymen who had been sojourning in Colorado and finally returned to England. As he landed in a fog and found himself home again, he exclaimed, "Thank God! I am out of that beastly sunshine." I do not suppose he intended to be irrational or ungrateful for the greatest of all natural gifts.

Now, what other climatic conditions besides pure air and abundant sunshine have we to help us? Is a cool climate or a warm climate the best? Is a dry or humid climate to be preferred? These quali-

ties of temperature and humidity may as well be considered together. Undoubtedly for the majority of cases in the first stage the climate should be dry and the temperature comfortable—not warm enough to be relaxing, but not so cold as to be repellent and restrict exercise or out-of-door life. It is true that in special localities better results are obtained during the cold months than during the summer. This is true of the Adirondack Cottage Sanitarium in the State of New York. One reason for this is that in winter the lakes and ponds are frozen and covered with dry snow; the air is drier. It is far enough north and at a sufficient altitude to escape the alternate freezing and thawing that is experienced in New York City, where unquestionably it is less favorable for the consumptive during the cold season than during the warm months. Take Florida and South Carolina: Undoubtedly the best season there is during the winter months, as the summers are oppressively warm and wet. The winter is the dry season and the temperature is comfortable. The interior of Florida forty or fifty miles from either coast is reasonably dry. As far as Arizona and New Mexico are concerned, the summers are too hot at all the lower elevations for any invalid, but at the higher elevations, 5,000 or 6,000 or 7,000 feet, the summer heat is not oppressive. Along the southern coast of California and at many of the resorts somewhat inland, as good results are obtained in summer as in winter, although the latter is the more fashionable season for eastern visitors. The southern California resorts which have been most frequented by consumptives vary greatly between themselves as regards the important question of humidity. That a place is frequented by consumptives does not prove that it is a desirable place for them. Many of them are misguided, wandering invalids, sent out from the east with little or no judgment as to their individual needs and with no proper knowledge on the part of their medical advisers as to the humidity or local character of the places to which they are destined. A man, for instance, will go to Los Angeles. It does not take him long to find out that while the air is fairly dry from 11 a. m. to 5 p. m., it is always damp at night. Six hours out of twenty-four are dry, the remaining eighteen are decidedly damp. The physicians of Los Angeles do not claim that their climate is a suitable one for cases of tuberculosis and usually send these cases to the interior stations, such as Redlands or Riverside, Monrovia or Altadena. Many are sent to Arizona. Experience shows that consumptives do better if they avoid the coast region. Or, if near the coast, as at Santa Barbara, they are better if they

find a site at some elevation on the hillside or in the mountain valleys beyond the reach of the morning fog and the excessive humidity at the shore.<sup>1</sup> The records of the Weather Bureau show that these places on the coast or within reach of the fogs which penetrate inland have a greater humidity than Boston or New York, the mean annual absolute humidity for Santa Barbara, Los Angeles, and San Diego being given at 4.20, 4.42 and 4.34 grains, more than one-third more than that of New York and Boston, 3.19 grains and 2.84 grains. The mean annual relative humidity of all these places mentioned is from 72 to 73 per cent. But the advantage of places like Santa Barbara, San Diego, Redlands, and Riverside, lies in the fact that the mean annual humidity shows a remarkable variation during the twenty-four hours compared with places like Boston, New York, or Philadelphia, where the daily range is much less. At Redlands, fifty miles inland from the Pacific Ocean, one of the best known stations, the hygrometer has been known to indicate in fair weather 55 per cent at 4.30 p. m., and 80 per cent at 6.00 p. m. The relative humidity is sometimes as low as 30 per cent for a limited time during the day, and 70 to 80 per cent at night when the temperature is from 44° to 60° F.

It may as well be stated that the government records of humidity are quite misleading when we use them to judge of the climate of any given place. The observations are made at 8 a. m. and 8 p. m., but in the invalid's day, made up of the intervening hours, the relative humidity reaches a much lower mark than the records show. I often observe a relative humidity in Virginia of 25 or 30 per cent at 2 p. m., and 95 or 98 per cent at night or in the early morning, especially when dew falls after a bright, invigorating day. I think that people, whether sick or well, adjust themselves to these natural changes of humidity if properly clothed and constantly in the open air; but when subject to rapid changes in humidity, as in going back and forth from the excessively dry air of a house in winter to the damp air outside, the demands upon the mucous membranes are very great and such frequent and violent changes certainly do harm to susceptible people. Such rapid variations or alterations of the humidity of the inspired air I think are as bad as would be rapid alternations of altitude involving variations of several thousand feet.

Some patients, however, seem to do better with a humidity greater than that chosen for others. If we have a low relative humidity

---

<sup>1</sup> See W. Jarvis Barlow, M.D.: *Climate in the Treatment of Pulmonary Tuberculosis* (Journ. Amer. Medical Association, October 28, 1911).

and at the same time a moderately low temperature the general effect is tonic and it is beneficial in conditions of irritability of the respiratory mucous membrane; but if the temperature is very low this may be rather irritating. We find atmospheric conditions like this from Minnesota to the Rockies and through Manitoba and Alberta.

The combination of high relative humidity and low temperature certainly favors catarrh and we have such conditions all winter long in the region of the Great Lakes and in New York and New England. Probably the best combination is a low humidity and a moderately cool temperature; the average tuberculous patient makes his best gains after August first and in subsequent cold, dry weather when such conditions prevail. But of course there are exceptions and some do better with a high relative humidity and a warm temperature; these are not numerous and probably include more of the patients in later stages when expectoration is profuse and vitality is low.

The old idea about equability of temperature, at least between the temperature of midday and midnight, is not of great importance; all mountainous stations show great variations in this respect. Some variability tends to stimulate the vital activities, but in older people and those who are feeble great variability is a disadvantage.

As far as altitude is concerned it probably has not, *per se*, any great influence; certainly to my mind not so much as we used to think. However, altitude is incidentally associated with mountain life or life on the plains, with more sun, less moisture, and scattered population. We should not forget that surgical tuberculosis is always favorably influenced by a seashore residence suitably chosen.

I never shall forget the wonderful impression made on visiting the Sea Breeze Hospital for Tuberculous Children on Long Island, New York. Constant outdoor life in all weather works miraculous cures after the most formidable operations for bone tuberculosis and in many cases renders them wholly unnecessary in patients whose physical condition on admission was most unpromising. All the great French and Italian sanatoria for tuberculous children are located on the seashore.

Among the numberless histories of the climatic cure I will give only one and I think I may safely let it stand as a good example by which to let the argument rest. The history is that of a physician whom we all love and respect. It was published, together with twenty other carefully recorded histories, by that prince of clinicians,

the late Dr. Alfred L. Loomis, in the Medical Record and formed a part of a paper read before the Medical Society of the State of New York in 1879, a paper which we commend to your attention. Dr. Loomis says:

At the age of twenty-five this patient, being of good family history, began to lose his health in the winter of 1872. His symptoms were rapidly becoming urgent; he was examined by several physicians. Extensive consolidation at the left apex was found, extending posteriorly nearly to the angle of the scapula; on the right side nothing was discovered save slight pleuritic adhesions at the apex.

He was ordered south, but returned in the spring in no way benefited. On the contrary, night-sweating had set in, and his fever was higher. In the latter part of May he started for the Adirondacks, the ride in the stage being accomplished on an improvised bed. His condition at this time was most unpromising; he had daily fever, night sweats, profuse and purulent expectoration, had lost his appetite and was obliged constantly to have recourse to stimulants. Weight about 134 pounds. He began to improve at once, his appetite returned, all his symptoms decreased in severity, and after a stay of more than three months he returned to New York weighing 146 pounds, with only slight morning cough, presenting the appearance of a man in good health. A few days after his arrival in New York he had a chill, all his old symptoms returned and he was advised to leave for St. Paul, Minnesota, where he spent the entire winter. He did badly there; was sick the greater portion of the winter. In the spring of 1873 he again went to the Adirondacks. At this time he was in a most debilitated state, was anemic, emaciated, had daily hectic fever, constant cough, and profuse purulent expectoration.

The marked improvement did not commence at once as it did the previous summer, and the first of September found him in a wretched condition. I then examined him for the first time and found complete consolidation of the left lung over the scapula and suprascapular space, with pleuritic thickenings and adhesions over the infraclavicular space. On coughing, bronchial rales of large and small size were heard over the consolidated portion of the lung. Over the right infraclavicular region the respiratory murmur was feeble, and on full inspiration pleuritic friction sounds were heard. I advised him to remain at St. Regis Lake during the winter, and although he was repeatedly warned that such a step would prove fatal, he followed my advice.

From this time he began slowly to improve. Since that time he has lived in this region. At the present time his weight is 158 pounds, gain of 22 pounds since he first went to the Adirondacks in 1873, and ten pounds more than was his weight in health. He has slight morning cough and expectoration, his pulse is from 72 to 85 and he presents the appearance of a person in good health. In his lungs evidences still remain of the disease he has so many years combated.

Although he has made three attempts to live in New York, at intervals of two years, each time his removal from the mountains has been followed within ten days by a chill, and a return of pneumonic symptoms—symptoms so ominous that he has become convinced that it will be necessary for him to remain in the Adirondack region for some time to come.

THE WALSH WINDOW TENT. ALTHOUGH LYING IN THE BEDROOM THE SLEEPER HAS FREE ACCESS TO THE OUTER AIR

We all know the after history of this patient. Thank God, he is still living, still working, and there are thousands living to-day who owe their lives to the example which he has set them. He seized the principles of climatic treatment and adapted it to the individual.

I recently sent the following question to the deans of medical colleges in Boston, Chicago, New Orleans, Los Angeles, and Montreal. I knew nothing of the views of these men on this subject except one; of course we all know that every one from California has decided views on climate. The question was:

What would you do for yourself climatically if you were told for the first time that you had incipient pulmonary tuberculosis?

Here are the answers:

I would strike for the wild pine woods of northern Michigan or Wisconsin and stay there.—A. R. Edwards, Chicago.

In answer to your question I may say that if I had incipient tuberculosis I should either go to Saranac or St. Agathe in Canada and employ the open air treatment.—F. J. Shepherd, McGill University, Montreal.

In answer to your question of December 26, I would say that I would treat myself as I do patients on whom I make the diagnosis of incipient pulmonary tuberculosis, that is, refer them to a local man who specializes in this disease, and ask him to look them over and refer them for climatic treatment in accordance with his knowledge of climatic conditions suitable to the individual case. Were I to start out to select a climate for myself, I would be much more influenced by the physician under whose care I would come in the new place than by the actual climate, and would probably select either Saranac Lake or Asheville, N. C., as I know and have confidence in physicians in each place. Were they to decide that I was better suited to some other climate, I would move on under their advice. If it were possible, I believe that I would undoubtedly leave Boston, had I incipient tuberculosis.

Very truly yours,

HENRY A. CHRISTIAN,

Boston.

If I had to answer your question categorically I would say that I would ask the advice of one or two men living in my own community as to what I should do for myself climatically if I were told for the first time that I had incipient pulmonary tuberculosis.

The practice among the profession in New Orleans is to send patients to St. Tammany Parish, in Louisiana, where the growth of piney woods is thick and ozone plentiful. When the particular case justifies, the patient is sent to the plains of Arizona or New Mexico, and, rarely, to El Paso, Texas. A few patients go to Colorado.—Isadore Dyer, Tulane University, New Orleans, La.

Perhaps I can best answer this personally by telling you what I did when I was told this very thing fifteen years ago. Having contracted tuberculosis in New York city I sought a better climate for an outdoor life, spending the first summer in the Adirondack Mountains and in November of that year

going to California, where I lived for one year in the foothill region near the coast at an elevation of 1,000 feet, free from responsibility and work. After the first year I never had any return of my pulmonary tuberculosis.

I believe a change of climate is more a question of finances than anything else. If one has not the necessary means to have what is right in a different climate his chances for a cure are much better with home treatment, but when a better climate can conveniently be added to other measures of treatment for pulmonary tuberculosis it should be advised.—W. Jarvis Barlow, Univ. of Southern California, Los Angeles, Cal.

NOTE.—For the bibliography of tuberculosis in its various relations the reader is referred to the Index Catalogue of the Surgeon-General's Library, U. S. Army, Volume 18, Second Series, Washington, 1913. This bibliography embraces 412 pages in double columns, an invaluable contribution to the history and literature of this subject.

NOTES ON SOME SPECIMENS OF A SPECIES OF  
ONYCHOPHORE (OROPERIPATUS CORRADOI)  
NEW TO THE FAUNA OF PANAMA

BY AUSTIN HOBART CLARK

Through Professor T. D. A. Cockerell I have recently received four specimens of a species of *Peripatus* collected at Ancon, Canal Zone, by Mr. J. Zetek, which represent a genus, as well as a species, not previously definitely known as an inhabitant of the region.

These specimens are now in the collection of the United States National Museum.

**OROPERIPATUS CORRADOI (Camerano)**

*Peripatus corradoi* 1898. CAMERANO, Boll. Mus. Zool. ed Anat. comp. di Torino, vol. 13, No. 316, p. 2.—1898. CAMERANO, Atti R. Acc. Sci. di Torino (2), vol. 33, pp. 308-310, figs. A and B; p. 591.—1905. BOUVIER, Ann. des. sci. nat. (9), vol. 2, p. 120, pl. 3, fig. 15; pl. 4, figs. 29, 30; text figs. 6, p. 15; 18, p. 20; 42, p. 38; 63, p. 124; 64 and 65, p. 125 (the complete synonymy is given).

*Oroperipatus corradoi* 1913. A. H. CLARK, Proc. Biol. Soc. Washington, vol. 20, p. 16.

*Locality*.—Ancon, Panama Canal Zone.

*Material*.—Four specimens, two males and two females.

*Notes*.—One of the females is 34 mm. long and 4 mm. broad, and possesses twenty-seven pairs of ambulatory legs; the other is 34 mm. long and 3.5 mm. broad, with twenty-nine pairs of ambulatory legs.

Of the males one is 19 mm. long and 2.3 mm. broad, with twenty-four pairs of ambulatory legs, and the other is 19 mm. long and 2.5 mm. broad, with twenty-five pairs of ambulatory legs.

All the specimens are dorsally dark brown in color, with a narrow median line of darker, and ventrally light brown.

The dorsal folds in the two females are all of approximately the same width, but in the males there is a more or less distinct alternation of broader and narrower folds; there are no incomplete folds.

Some of the primary papillae of the back are very much more developed than the others, and lighter in color, and these enlarged light colored papillae show a more or less regular arrangement which, however, is very much less evident in the females than in the males.

There is a regular line of these papillæ on either side of the median dorsal dark line, which gradually becomes irregular and disappears somewhat before the middle of the body. There are two scalloped rows, one along each of the outer margins of the dorsal surface of the body, consisting of a series of arcs of which the convexity is above each of the ambulatory legs; beyond these in the males there are similar lines with the arcs alternating with those in the inner rows, their convexity being between the legs, and reaching down to the level of the leg bases. Between the median and lateral lines the enlarged papillæ are arranged in a sinuous and more or less irregular line, with scattered ones on either side of it; but toward the posterior part of the body they become less and less numerous, and more and more irregular in their position.

All of the legs are provided with feet.

The creeping pads consist each of four arcs of nearly equal width, of which the fourth is about as long as the second.

The urinary tubercle which, in reference to the short diameter of the third arc is approximately central in position, divides the third arc into two parts, of which the posterior is much smaller than the anterior, and is entirely separated from the tubercle, which is broadly united with the anterior portion. The conditions in these specimens is well represented in Bouvier's figure.

*Remarks.*—These individuals appear to agree with the specimens of *Oroperipatus corradoi* from Guayaquil as described by Bouvier.

*Range.*—*Oroperipatus corradoi* is now known from Quito, Balzar and Guayaquil, Ecuador, and from Ancon, Panama Canal Zone.

*List of the Species of Onychophores Known from the Isthmus  
of Panamá*

*Oroperipatus corradoi* (Camerano).

*Oroperipatus eiseni* (Wheeler)<sup>1</sup>.

*Macroperipatus geayi* (Bouvier).

*Epiperipatus brasiliensis* (Bouvier).

*Epiperipatus edwardsii* (Blanchard).

<sup>1</sup> This species has not actually been taken on the isthmus, but as it ranges from Tepic, Mexico, south to the Rio Purus, Brazil, it probably occurs there.

A NEW CERATOPSIAN DINOSAUR FROM THE UPPER  
CRETACEOUS OF MONTANA, WITH NOTE  
ON HYPACROSAURUS<sup>1</sup>

BY CHARLES W. GILMORE

ASSISTANT CURATOR OF FOSSIL REPTILES, U. S. NATIONAL MUSEUM.

(WITH TWO PLATES)

INTRODUCTION

The fossil remains upon which the present communication is based were collected by the writer during the summer of 1913 while working under the auspices of the U. S. Geological Survey on the Blackfeet Indian Reservation in northwestern Montana. The partial skeletons of five individuals were found and these supplement one another to such an extent that nearly all parts of the skeleton are represented. The skull presents some anatomical features not heretofore known in the Ceratopsia and the new genus and species *Brachyceratops montanensis* is here proposed.

This new form is the smallest known representative among the Ceratopsian dinosaurs and in several respects strikingly different from any of its allied contemporaries.

The present paper is preliminary. Upon the completion of the preparatory work now in progress a more detailed account of the skeletal anatomy and a discussion of its affinities will be given.

**BRACHYCERATOPS MONTANENSIS**, new genus and species

*Type*.—Cat. No. 7951 U. S. Nat. Mus. A considerable portion of a disarticulated skull (*i. e.*, nasals, prefrontals, postfrontals, postorbitals, premaxillaries, maxillaries, alisphenoid), with which is provisionally associated a fragmentary part of the frill and a right dentary and a predentary.

*Type locality*.—N. E.  $\frac{1}{4}$  Sec. 16, T 37 N, R 8 W, Milk River, Blackfeet Indian Reservation, Teton County, Montana.

*Paratypes*.—Cat. No. 7952, U. S. Nat. Mus. Rostral and portions of the premaxillaries; Cat. No. 7953 U. S. Nat. Mus. Sacrum.

<sup>1</sup> Published by permission of the Director of the U. S. Geological Survey.

complete pelvis and articulated caudal series of 45 vertebræ continuing to the tip of the tail; Cat. No. 7957, U. S. Nat. Mus. Two tarsals of the distal row, four articulated metatarsals, a portion of the fifth, and eleven phalanges.

*Localities.*—Same as the type.

*Horizon.*—From the upper part of an Upper Cretaceous formation soon to be described by the U. S. Geological Survey, which includes the equivalent of the Judith River formation and some older beds. The fossiliferous horizon is also the equivalent of the upper part of the Belly River formation, as described in neighboring areas of Canada.

*Generic and specific characters.*—Typically of small size. Skull with facial portion much abbreviated, and deep vertically. Supra-orbital horn cores small. Nasal horn core outgrowth from nasals, large, slightly recurved, laterally compressed, and divided longitudinally by median suture. Frill with comparatively sharp median crest, fenestræ apparently of small size, and entirely within the median element. Supratemporal fossæ opening widely behind. Border of frill scalloped, but without separate marginal ossifications. Dentition as compared with *Triceratops* greatly reduced.

*Description of skull.*—The description to follow is devoted entirely to a consideration of the skull, since it shows characters of sufficient importance to readily distinguish it from all the other known members of the Ceratopsian group, which in the greater number of instances have also been established upon cranial material.

When found, the skull was entirely disarticulated, but the excellent state of preservation of the bone and the absence of distortion by crushing rendered the assembling of the scattered elements a comparatively easy matter. This specimen is of the utmost importance in the evidence it gives for the proper interpretation of the cranial elements, and especially the positive information it affords relating to those parts of the Ceratopsian cranium now somewhat in controversy.

In the above diagnosis of the genus and species, it is stated to be typically of small size. While this statement is true so far as applied to the known specimens, it should also be stated that to some extent the small size of these specimens may be due to the immaturity of the individuals. The open sutures of the skull, sacrum, and vertebræ all testify to the youth of the animals.

Viewing the skull in profile (pl. 1), one is especially impressed by the great abbreviation of the facial portion, when compared with the

Ceratopsians of the Lance formation. It is to this shortening that the generic name refers. The narial opening, as in other known Judith River and Belly River forms, is situated well forward and under the nasal horn, whereas in the later and more highly specialized *Triceratops* this orifice is entirely posterior to that horn. The distance between the nasal and supraorbital horns, as seen in the upper outline, is exceedingly short, due largely to the shortened nasal bones and the great fore and aft development of the basal portion of the nasal horn and also to the forward position over the orbits of the small brow horns.

The exact pitch of the frill portion in relation to the anterior part of the skull cannot be positively determined, though in the drawing it has been placed in accordance with the evidence of articulated skulls.

This specimen brings to light an entirely new phase of nasal horn development and one which, so far as our previous knowledge goes, appears to be unique among dinosaurs. Reference is made here to the longitudinal separation of the horn core into two halves by the nasal suture. This also indicates the nasal horn to be an outgrowth from the nasal bones instead of having originated from a separate center of ossification, as is the case in the more specialized *Triceratops*. It appears quite probable there are some of the described Belly River species that will also show a similar mode of nasal horn development when juvenile specimens are found.

The nasals are especially deep and massive, due to the development on their superior surfaces of the nasal horn cores. Posteriorly they present a pointed process with a beveled underlapping surface for contact with the prefrontals (the frontals and lacrymals of authors). Laterally they send down a deep extension to meet the premaxillary, and anteriorly the arched ventral borders of the nasal bones form the upper half of the boundary of the narial orifice. Anteriorly they send out vertically flattened processes (see *p*, fig. 1) between which are received the ascending processes of the premaxillæ. This nasal process appears to end about 32 mm. in advance of the forward line of the horn core, so that the upper outline of the beak is formed largely by the premaxillaries. The horn has a broad fore and aft extent at its base, but tapers rapidly to a bluntly pointed horn of moderate height. Transversely it is much compressed at the base, though inclined to expand somewhat toward the summit. The horn as a whole is directed somewhat forward, but the curve of the posterior side is such as to give the impression

that its upper part is slightly recurved. The surfaces of the upper half are roughened and grooved by vascular impressions.

On the tip of the left half of the nasal horn is a small, flattened oval bony ossicle, which rests in a shallow depression or pit on the apex of the horn as shown at *os*, figure 1. This ossicle is a distinct element from the underlying bone and may represent the incipient horn of later Ceratopsians where it is known to be developed from a center of ossification distinct from the nasal bones.

FIG. 1.—Nasals and nasal horn cores of *Brachyceratops montanensis*. Type: Cat. No. 7951 U. S. Nat. Mns.,  $\frac{1}{2}$  Nat. size. A, side view; B, front view; *c*, surface for contact with the premaxillaries; *f*, surface for articulation of prefrontal; *no*, anterior nasal opening; *os*, ossicle on top of horn core; *p*, anterior process of nasal; *po*, orifice for superior processes of premaxillaries; *s*, suture separating two halves of nasal horn.

The maxillaries are of triangular outline with alveoli for twenty teeth in the functional row. As compared with *Triceratops* this is a greatly reduced number, *Triceratops* having forty alveoli in the maxillary. In this specimen all of the functional teeth have fallen out, but two or more germ teeth are still retained and these give some idea of their character.

The true extent of the postfrontals in the Ceratopsian skull is here correctly determined for the first time. Authorities have heretofore considered the postfrontal as extending from the median line outward and including all of that portion of the skull here designated as postfrontal and postorbital (see pl. 2). In this specimen a longitudinal suture just internal to the base of the supraorbital horn core separates it into two distinct elements. The inner portion all paleontologists agree in calling the postfrontal, the outer appears without question to represent the postorbital. Von Huene,<sup>1</sup> in 1912, in a skull of *Triceratops prorsus* regarded that portion forming the posterior boundary of the orbit as representing the whole of the postorbital, but the writer now questions the correctness of this determination in the genus *Triceratops*, in so far as regarding it as representing the entire postorbital.

In *Brachyceratops* the postfrontal is a somewhat irregularly triangular bone, longer than wide, which unites by suture on the median line with its fellow of the opposite side.

Anteriorly the combined postfrontals terminate in a pointed projection that is interposed between the deeply emarginate posterior borders of the prefrontals. Posteriorly and on either side of the postfrontal foramen these bones articulate by suture with the median element of the frill. A toothed external border unites with the postorbital. Beginning between the horn cores the median upper surfaces of the postfrontals are angularly depressed, gradually deepening and widening transversely as they approach the fontanelle much as in *Styracosaurus albertensis* Lambe, see B, plate II, *The Ottawa Naturalist*, Vol. 27, 1913.

The postorbital gives rise to the small supraorbital horn core and forms nearly one-half of the orbital border. Posterior to this horn which is situated on the extreme anterior end, the bone flares out into a wide expanded portion, much deflected externally, with a curved posterior border, the inner half of which forms a portion of the outer boundary of the supratemporal fossa, the outer half having an underlapping sutural edge for articulation with the squamosal. The straight inferior edge meets the jugal which is missing in this specimen.

The thickened anterior border shows a sutural edge for union with the missing supraorbital bone. On the median inferior surface is a shallow pit which receives the outer end of the alisphenoid, as it does in *Stegosaurus* and *Camptosaurus*.

---

<sup>1</sup> Neues Jahrbuch, 1912, fig. 3, p. 151.

Immediately above the orbit on the anterior part of the postorbital there rises a low horn core, the upper extremity being obtusely rounded from a lateral aspect, see *po.h* plate 1, but sharply pointed when viewed from the front. The external surface of this horn is plane, the internal strongly convex, with the antero-posterior diameter greatly exceeding the transverse, the total height of the horn above the orbit being 35 mm. These horn cores appear to be outgrowths from the postorbital bones unless they include a posterior supraorbital element such as has recently been found in the skull of *Stegosaurus*. However that may be, there is no trace of such a division in the postorbitals of this specimen. This again raises the question of the proper designation of these horns which have been called successively postfrontal and supraorbital horn cores. If an outgrowth from the postorbital bone, as the present specimen appears to indicate, the term postorbital horn core would be a more appropriate designation.

The prefrontals (the frontals and lacrymals of authors) are deeply emarginate anteriorly and receive between them the pointed posterior ends of the nasals.

The prefrontal is a quadrangular plate of bone diagonally placed filling the interspace between the postfrontal and nasal bones. Its thickened posterior end contributes to the inner part of the anterior boundary of the orbit. Near the posterior termination a narrow vertical sutural surface (*so*, pl. 2) on the external side was for the articulation of the small supraorbital bone that is missing. This element would have completed the thickened projecting orbital border immediately in front of the eye and which forms such a conspicuous feature of the Ceratopsian skull. On the upper posterior end of the prefrontal a pointed peg-like projection is received in a corresponding pit in the anterior border of the postfrontal, thus strengthening the union of these two bones. The prefrontal is just barely in contact with the postorbital at the base of the postorbital horn core.

The relationships of the pre- and postfrontals in *Brachyceratops* is an unusual one, for in most dinosaurian crania the frontal is interposed between them, and so far as the writer is aware the above condition is only found in *Stegosaurus* among the dinosauria and in some of the Permian reptilia. Von Huene has shown, and the writer believes correctly too, that the frontal in *Triceratops* has been entirely excluded from the dorsal surface of the skull.

The frill is represented by the median elements from two individuals. Both have portions missing, but the better preserved one is

provisionally associated with the type as shown in plates 1 and 2. This association, however, is only provisional in so far as it applies to the recognition of the proper individual, for it can be said without question that all the bones found belong to the same kind of an animal.

The dermo-supraoccipital or interparietal, for surely it cannot be the parietal as Hay<sup>1</sup> and von Huene<sup>2</sup> have clearly shown, is united by suture with the anterior portion of the skull at the postfrontal foramen. The median part of the interparietal is sharply ridged, excepting the posterior extremity, where it flattens out into a thinner portion with an emarginate median border. Between the fenestræ the median bar, in cross section, is triangular. The superior surface of this ridge forward of its narrowest part between the fenestræ presents three low longitudinal swellings arranged one in front of the other. Proximally the median portion is greatly compressed transversely into a short neck, forward of which it again widens into a much depressed end that articulates laterally with the postfrontals and with them forms the upper boundaries of the postfrontal foramen, see *fo*, plate 2. Between these two lateral portions the median surface is deeply concave and slopes downward to a heavy truncated border that in all probability was suturally united with the parietals. In *Brachyceratops* at least, the parietal was entirely excluded from the dorsal aspect, and it is presumed that similar conditions obtained in *Triceratops*, although von Huene was inclined to regard a small portion of the median part of the frill posterior to the postfrontal foramen in that genus as being parietal.

The bone surrounding the frill fenestræ is very thin, but toward the lateral free edges and posteriorly it becomes thickened. Proximally it remains thin where it forms the floor of the supratemporal fossa but thickens toward the sutural border for the squamosal. The exact shape and extent of the frill fenestræ cannot be accurately determined from the available specimens, but it is readily apparent that they were of comparatively small size. The surfaces of the frill are relatively smooth and without the ramifying system of vascular grooves of the later Ceratopsians. There were no epoccipital bones on the margins of the frill, but on either side of the median emargination a series of prominences give to the periphery much the same peculiar scalloped effect found in the *Triceratops* frill with its separate ossifications.

<sup>1</sup> Proc. U. S. Nat. Mus. vol. 36, 1909, p. 97.

<sup>2</sup> Neues Jahrbuch, 1912, pp. 150-156, figs. 3, 4, 5 and 6.

Laterally the median portion unites with the squamosal by a straight sutural edge that is directed forward and inward toward the center of the skull. A triangular outward projection with an upper striated surface at the anterior termination of the squamosal suture represents a surface that was overlapped by the articulated squamosals (*s.s.*, plate 1). A low, sharp, diagonally directed ridge apparently indicates the posterior extent of the overlap of the squamosal. The squamosals are missing, but those as in other primitive Ceratopsians appear to have been short and broad.

The rostral is missing from the type, but is present in a slightly smaller individual (Cat. No. 7952, U. S. Nat. Mus.). (See fig. 2.) In general aspect it resembles the rostral of *Triceratops*, but with a

FIG. 2.—Rostral of *Brachyceratops montancensis*. Paratype; Cat. No. 7952 U. S. Nat. Mus.,  $\frac{1}{2}$  nat. size. *a*, side view; *b*, posterior view; *s*, superior process; *p*, posterior processes.

less curved anterior border. Externally the surfaces are pitted and grooved and in life were doubtless covered by a horny sheath.

The prementary except for its much smaller size is indistinguishable from that of *Triceratops*. It is to be distinguished from the prementary of *Monoclonius dazsoni* Lambe by the upward turned apex of the anterior end.

The dentary is stout, gradually narrowing vertically toward the front, the anterior end being especially depressed and unusually broad transversely, this end being nearly at right angles to the posterior portion. Near the posterior end on the external surface a stout coronoid process is developed, extending well above the dental border. It is compressed transversely but widens antero-posteriorly with a hooked forward process as in other primitive Ceratopsians. Beginning at the base of this process, a low, broad ridge extends

forward at about mid-height along the outer side of the dentary. Above and below this ridge the outer surface retreats obliquely inward.

Viewed from above, the dental border is straight but is obliquely placed in relation to the lower portion, that is, it passes from the inner posterior margin to the outer anterior margin of the jaw. Beneath the coronoid process there is a deep mandibular fossa which extends forward about one-third the length of the dentary. On the inner side there is the usual row of foramina, leading into the dental chamber. The exact number of alveoli cannot be determined at this time, although the tooth series is relatively shorter than in either *Ceratops* or *Triceratops*.

FIG. 3.—Dentary of *Brachyceratops montanensis*. Type: Cat. No. 7951 U. S. Nat. Mus.,  $\frac{1}{2}$  nat. size. c, coronoid process; m, mental foramen; sp, surface for pre-dentary.

At this time little can be said regarding the affinities of *Brachyceratops*, though it would appear most nearly allied to *Monoclonius*, as shown by its small size, the small brow horns of similar shape, large nasal horn and crenulated margin of the frill without separate marginal ossifications.

It is readily distinguished, however, from all known Ceratopsians by the longitudinal suture of the nasal horn, the small fenestra wholly within the median frill element, and the greatly abbreviated facial portion of the skull. It is also apparent that there are other distinguishing features in the skeleton which is to be described later.

The striking resemblance of the fragment of a skull figured by Hatcher as *Monoclonius crassus*<sup>1</sup> to the homologous parts of the

<sup>1</sup>Monog. U. S. Geol. Survey, Vol. 40, 1907, p. 74, fig. 76.

present specimen leads the writer to suggest its possible identification with the present genus. Hatcher regarded it as belonging to a smaller and distinct individual from the type of that species and he also observes: "I describe and figure this element in this connection not out of regard for any certain additional characters it may furnish distinctive of the present genus and species [*Monoclonius crassus*] but rather for the information which it affords relative to the homologies of certain cranial elements in the Ceratopsia as a group." The great similarity of the horn-cores with those of *Brachyceratops* lends much color to the above suggestion.

## MEASUREMENTS

## NOTE ON HYPACROSAURUS

I wish to announce the discovery in northwestern Montana, in beds equivalent to the upper part of the Belly River formation, of the Trachodont reptile *Hypacrosaurus*.<sup>1</sup> A considerable portion of the skeleton (Cat. No. 7948, U. S. Nat. Mus.) of one individual was recovered, and at this time (the specimen not being entirely prepared) I am unable to distinguish it specifically from the type and only known species, *H. altispinus* Brown, from the Edmonton Cretaceous of Canada.

<sup>1</sup> Barnum Brown: A New Trachodont Dinosaur Hypacrosaurus, from the Edmonton Cretaceous of Alberta. (*Bull. Amer. Mus. Nat. Hist.*, Vol. 32, 1913, pp. 395-406.)

ON THE RELATIONSHIP OF THE GENUS AULACOCARPUS,  
WITH DESCRIPTION OF A NEW PANAMANIAN SPECIES

By H. PITTIER

The genus *Aulacocarpus*, as originally regarded<sup>1</sup> by its founder, Dr. O. Berg, included two species, *A. Sellowianus* Berg, from Brazil, and *A. crassifolius* (Benth.) Berg, from Colombia. The latter was first described as *Campomanesia crassifolia* Benth.,<sup>2</sup> upon material collected by the botanists of the *Sulphur* voyage on Gorgona Island, off the Pacific coast of Colombia, between Buenaventura and Tumaco. The Flora of the British West Indies by Grisebach contains<sup>3</sup> the description of a new species, *A. quadrangularis*, from Antigua and Guadeloupe Islands; and subsequently the same author added his *A. Wrightii*, originally collected in Eastern Cuba.<sup>4</sup>

Thus, in 1866 *Aulacocarpus* had been increased to four species,<sup>5</sup> but the flower of none of these had ever been described. Taking into consideration the general distribution of the Myrtaceae, it was but logical, in the absence of more complete information, to find a place for this genus among the Myrtoideae, which are widely dispersed in America. According to Berg, its affinities were with *Campomanesia*, a supposition which was strengthened by the original inclusion in this genus of one of the species of *Aulacocarpus*. On the other hand, Niedenzu, taking as a basis the embryonic characters, places it among the *Eugeniinae*.

During his exploration of the forests of Eastern Panama, in 1911, the writer had the good fortune to discover a new representative of *Aulacocarpus* in the shape of a medium-sized tree, from which herbarium specimens were obtained, the flowers being preserved in alcohol. The description of these shows that, contrary to every expectation, *Aulacocarpus* is not a true Myrtoid, but must be placed among

<sup>1</sup> *Linnaea* 27: 345. 1856. Martius, *Fl. Bras.* 14<sup>1</sup>: 380. 1857.

<sup>2</sup> *Bot. Voy. Sulphur* 97. pl. 37. 1844.

<sup>3</sup> Page 239.

<sup>4</sup> *Cat. Pl. Cub.* 90. 1866.

<sup>5</sup> Niedenzu, however, ignores Grisebach's Antillean species (*Engl. & Prantl, Pflanzenfam.* 3<sup>r</sup>: 83. 1898).

the Leptospermoideae, also represented in South America by the Chilean genus *Tepualia*. This will be made clear by the following amended and completed description:

**AULACOCARPUS** Berg.

Receptacle forming a crater-like cup above the ovary. Sepals 5, short, obtuse or acute. Petals 5, unguiculate, apiculate. Stamens 10, inserted on the margin of the receptacle, 5 opposite to, 5 alternate with the sepals, curved outward beyond the corolla, the basifixed 2-celled anthers hanging around the receptacle; anther cells longitudinally dehiscent. Ovary 5-celled, each cell with 5 (or 4) ovules; style simple, truncate. Drupe depressed-globose, horny or sublignose, 5 to 1-celled, each cell with 1 seed. Seed albuminose, covered with a thick, suberose testa. Cotyledons plano-convex, thick; radicle basal, very short. Trees with very hard wood; leaves opposite, exstipulate, thick, obscurely veined; flowers single or few in a cluster, pseudo-axillary.

Species 5, Tropical American.

On account of its fundamental characters, viz.: exalbuminose seed, short basal radicle, ovate-depressed seeds, indehiscent woody drupe, 5-celled ovary, and 10 stamens, with basifixed anthers, *Aulacocarpus* would take perhaps an intermediary position between the *Calothamninae* and the *Chamaelauciae*. The genus does not naturally fit into any of the present divisions of the Leptospermoideae, although there can be no doubt as to its belonging to this subfamily.

The collection and study of new materials of the 4 species of *Aulacocarpus* already described is highly desirable and it is not unlikely that a better knowledge of the genus will result in a reduction of the number of species. My own specimens do not agree with any existing description, and so I have presumed to describe them under a new name.

**AULACOCARPUS COMPLETENS, sp. nov.**

A tree up to about 18 meters high and 35 to 40 cm. in diameter at the base. Crown elongate; trunk continuous. Bark smooth, grayish. Entirely glabrous.

Leaves opposite, large, coriaceous, short-petiolate. Stipules none. Petioles thick, 4 to 5 mm. long. Leaf blades 14 to 25 cm. long, 5 to 11 cm. broad, ovate-elliptic (broader toward the base), cordate to

truncate at the base, narrowly acuminate at tip, light green above, paler and sometimes brownish beneath. Costa impressed above, very prominent beneath; primary veins numerous, almost straight and parallel, slightly prominent above and underneath.

Flowers single or aggregate at nodes on old wood (never on the year's growth). Pedicels slender, 12 to 15 mm. long, bearing at the middle one pair of small bractlets, these clasping, ovate-acute, persistent, about 2 mm. long. Receptacle funnel-shaped or obconic, growing much above the ovary. Sepals 5, coriaceous, thick, ovate-triangular and acute at the tip, caducous, about 6 mm. long and 4 mm. broad at the base. Petals 5, reflexed, pink, irregularly and broadly ovate, apiculate, with a short, broad claw and a pair of rounded basal winglets; margin irregularly denticulate or sublacerate; length 11 mm., breadth 9 mm. Stamens 10, inserted on margin of receptacle and alternately opposite to sepals and petals; filaments about 10

Floral details of *Aulocarpus completens*: *a*, petal; *b*, stamen; *b*<sup>1</sup>, anther, ventral side; *b*<sup>2</sup>, anther, dorsal side; *c*, cross-section of ovary. Enlarged 4 times.

mm. long, bending outwards; anthers 6 to 6.5 mm. long, golden yellow, basifixed, introrse, with a large ovate, glandular, porelike structure at about the middle of the ventral side, and four small glands near the tip; cells longitudinally dehiscent. Ovary 5-celled, each cell with 5 or 4 ovules; style glabrous, terete, truncate, about 7.5 mm. long.

Fruit dry, 4 to 1-celled, globose-depressed in the first case, with the cells showing outside, globose and crowned with the cuplike receptacular overgrowth when 1-celled; pericarp thick, hard, greenish outside at maturity; cells 1-seeded. Seeds large, ovoid and slightly compressed laterally, their length 11 mm., the longest diameter 9 mm.

PANAMA: Hills back of Puerto Obaldia, San Blas Coast; flowers and fruit, August 30, 1911; *Pittier* 4310 (type, U. S. Nat. Herb. Nos. 479435-7).

This remarkable species differs from *A. crassifolius* (Benth.) Berg in its larger leaves, these almost always deeply emarginate at the base, and in having the lobes of the calyx long, acute, triangular, and caducous. Further, our species is a relatively large tree, while the latter, compared in its habit with *Calycolpus glaber*, is barely more than a shrub. The wood is very hard and known under the name "gasparillo."

BALTIMORE, MD., U. S. A.

DESCRIPTIONS OF FIVE NEW MAMMALS FROM  
PANAMA

By E. A. GOLDMAN

Additional determinations of mammals obtained by the writer, while assigned to the Smithsonian Biological Survey of the Panama Canal Zone, reveal five hitherto unrecognized forms which are described below.

For the loan of types and other material for comparison I am indebted to Dr. J. A. Allen of the American Museum of Natural History, New York City, and to Mr. Samuel Henshaw of the Museum of Comparative Zoology, Cambridge, Massachusetts.

**CHIRONECTES PANAMENSIS**, new species

*Type* from Cana (altitude 2,000 feet), eastern Panama. No. 179164, skin and skull, male, old adult, U. S. National Museum (Biological Survey Collection); collected by E. A. Goldman, March 23, 1912. Original number 21562.

*General characters*.—Similar to *C. minimus* of Guiana in size and color, but differing in cranial details, especially the longer braincase and much longer, evenly tapering, and posteriorly pointed nasals.

*Color*.—Color pattern about as in *C. minimus*, but light facial areas apparently less distinct; dark brown or black of forearms extending down over the thinly haired first phalanges of three median digits, the terminal phalanges white or light flesh color as in *minimus*; hairy base of tail dark all round.

*Skull*.—Similar to that of *C. minimus*, but braincase more elongated, the well-developed lambdoid crest projecting posteriorly over foramen magnum; nasals longer, encroaching farther on frontal platform, the ends pointed instead of truncate, and the sides not constricted near middle; ascending branches of premaxillae reaching farther posteriorly along sides of nasals; fronto-parietal suture convex posteriorly; inner sides of parietals longer; sagittal crest well developed.

*Measurements*.—Type: Total length, 651 mm.; tail vertebrae, 386; hind foot, 72. *Skull* (type): Greatest length, 74.2; condylo-basal length, 72.3; zygomatic breadth, 43.8; length of nasals, 33;

greatest breadth of nasals, 11; interorbital breadth, 14.1; postorbital breadth, 8.5; palatal length, 45.6; upper molariform tooth row, 26.4; upper premolar series, 11.6.

*Remarks.*—While the water opossum of Middle America and Colombia is very similar in size and color to *C. minimus* of north-eastern South America it differs in numerous cranial details from that animal as figured by Burmeister.<sup>1</sup> The nasals are conspicuously longer and very different in form. The sagittal crest develops in both sexes early in life. In a specimen from Rio Frio, Cauca River, Colombia, the tail is black to the tip.

*Specimens examined.*—Total number, 11, as follows:

Panama: Cana (type), 1.

Costa Rica: San Jose, 1; exact localities unknown, 3.

Nicaragua: Matagalpa, 1.

Colombia: Bagado, 1; Barbacoas, 1; Guanchito, 1; Porto Frio, Cauca River, 1; Palmira, 1.

#### LONCHOPHYLLA CONCAVA, new species

*Type* from Cana (altitude 2,000 feet), eastern Panama. No. 179621, skin and skull, male adult, U. S. National Museum (Biological Survey Collection), collected by E. A. Goldman, May 20, 1912. Original number 21701.

*General characters.*—Similar in size to *L. mordax*, but color darker; cranial and dental characters different, the second upper premolar notably narrower, and in the reduced development of the internal lobe more like that of the much larger species, *L. hesperia*.

*Color.*—About as in *Glossophaga soricina*; general color of upper parts near warm sepia (Ridgway, Color Standards and Nomenclature, 1912), the under parts and basal color of fur of upper parts somewhat paler.

*Skull.*—Broader and more massive than that of *L. mordax*, the braincase larger and more fully inflated; interpterygoid fossa broader; coronoid process lower, the upper outline more broadly rounded; angle of mandible longer; incisors slightly larger; second upper premolar much less extended transversely owing to reduction in size of inner lobe; molar crowns more quadrate, less triangular in outline. Compared with that of *L. hesperia* the skull is much smaller and relatively shorter and broader, the braincase relatively larger but flatter above; coronoid process with less broadly rounded

<sup>1</sup> Fauna Brasiliens, pp. 72-73, pl. 11, figs 3-4, 1856.

upper outline; dentition similar, but relatively heavier, the premolar series less widely spaced; third upper molar nearly as large as second (decidedly smaller in *hesperia*).

*Measurements.*—Type (measured in flesh): Total length, 68 mm.; tail vertebrae, 10; tibia, 12.7; hind foot, 11; forearm, 33.9. *Skull* (type): Greatest length, 23.4; condylobasal length, 22.4; interorbital breadth, 4.6; breadth of braincase, 9.3; mastoid breadth, 9.8; depth of braincase at middle, 6.9; palatal length, 12.3; length of mandible, 16.8; maxillary tooth row, 8.

*Remarks.*—In the general form of the skull this species is in all essential respects like *L. mordax* and *L. robusta* and unlike *L. hesperia* in which the skull is relatively much narrower and more elongated. The narrowness and *Chaeronycteris*-like appearance of the skull of *L. hesperia* has been pointed out by Mr. Gerrit S. Miller, Jr.<sup>1</sup> The greater relative as well as actual length of the rostrum in *hesperia* leaves the third upper molar implanted well in front of the maxillary processes of the zygoma as in the genus *Chaeronycteris* instead of in the same horizontal plane with these processes as in *mordax* and *robusta*. In the narrowness of the second upper premolar, however, *L. concava* approaches *hesperia*, the conspicuous inner lobe present in *mordax* and *robusta* being reduced to a slight swelling bearing a small cusp. The coronoid process in *concava* is somewhat intermediate in shape between the high angular form seen in *mordax* and the low, broadly rounded upper outline of *hesperia*.

A small bat, *Lionycteris spurrelli*, from northwestern Colombia, has recently been described by Mr. Oldfield Thomas and made the type of a new genus characterized by the narrowness of the upper premolars. *L. concava* may possibly require comparison with the Colombian species which is based on an immature individual. But, allowing for immaturity, the cranial dimensions given are so different (greatest length, 18.7 in *spurrelli*, 23.4 in *concava*) that the specific identity of the two seems very improbable.

*Specimens examined.*—One, the type.

#### LUTRA REPANDA, new species

*Type* from Cana (altitude 2,000 feet), eastern Panama. No. 179974, skin and skull, male adult, U. S. National Museum (Biological Survey Collection), collected by E. A. Goldman, May 30, 1912. Original number 21758.

<sup>1</sup> Proc. U. S. Nat. Mus., vol. 42, No. 1882, p. 24, March 6, 1912.

*General characters.*—A small form with low, flat skull closely allied to *L. colombiana*, but differing in dental and slight cranial characters, especially the lesser transverse extent of the large upper molariform teeth. Differing from *L. latidens* in much smaller size as well as cranial details.

*Color.*—Entire upper parts warm sepia or mars brown (Ridgway, 1912); under parts grayish brown, palest on throat, pectoral and inguinal regions; lips and inner sides of forelegs soiled whitish.

*Skull.*—Similar in size to that of *L. colombiana*; rostrum and interorbital space narrower; lachrymal eminence more prominent, projecting as a distant process on anterior border of orbit; jugal less extended vertically but bearing a postorbital process as in *colombiana*; palate reaching farther posteriorly beyond molars; upper carnassial narrower, with inner lobe less produced posteriorly, leaving a gap which is absent in *colombiana*; upper molar narrower, the postero-external cusp set inward, giving the crown a less evenly rectangular outline. Contrasted with that of *L. latidens* the skull is very much smaller, with flatter frontal region.

*Measurements.*—Type: Total length, 1085 mm.; tail vertebrae, 500; hind foot, 119. An adult female from Gatun, Canal Zone: 1095; 463; 111. *Skull* (type): Condylobasal length, 109.1; zygomatic breadth, 72; interorbital breadth, 23.1; postorbital breadth, 16.8; mastoid breadth, 69.9; palatal length, 49.8; maxillary tooth row, 36.1; alveolar length of upper carnassial, 12.4; alveolar breadth of upper carnassial, 10.

*Remarks.*—The otter of Panama, like other Middle American forms of *Lutra*, has the nose pad haired to near the upper border of the nostrils; the soles of the feet are entirely naked; the tufts of hair under the toes and the granular tubercles present on the soles of the hind feet in *L. canadensis* are absent. The frontal region is flatter in skulls of *L. repanda* than in the skull of the type of *L. colombiana*, but the more swollen condition of the latter may be due to the presence of the parasites that frequent the frontal sinuses in *Mustelidae*.

*Specimens examined.*—Two, from localities as follows:

Panama: Cana (type), 1.

Canal Zone: Gatun, 1.

#### FELIS PIRRENSIS, new species

*Type* from Cana (altitude 2,000 feet), eastern Panama, No. 179162, skin and skull, female adult, U. S. National Museum (Biological Survey Collection); collected by E. A. Goldman, March 22, 1912. Original number 21559.

*General characters.*—A large, long-tailed tiger-cat, probably a member of the *F. pardinoides* group. Pelage rather long and soft; fur of nape not reversed; skull large with narrowly spreading zygomatica and fully inflated audital bullae.

*Color.*—Ground color of upper parts ochraceous tawny (Ridgway, 1912), nearly uniform from nape to base of tail, but becoming somewhat paler on head and paling through cinnamon buff to pinkish buff along lower part of sides; general upper surface heavily lined and spotted with black, the spots on sides more or less completely encircling tawny areas, or forming rosettes; back of neck with a narrow median black line and two broader parallel lines, one on each side; shoulders marked by heavy diagonal stripes extending from near a rounded solid black median spot downward and forward on each side; posterior part of back with two narrow central lines extending to near base of tail; under parts white, heavily spotted with black across abdomen, and with black bars, one across throat and one across neck; outer sides of forearms and hind legs cinnamon buffy, spotted with black; feet buffy grayish interrupted by small black markings; ears deep black, with white submarginal spots and buffy edges; tail with about 12 broad, irregular, but nearly complete black rings, the narrow interspaces buffy above and white below.

*Skull.*—Large and rather elongated, the vault of braincase highest near fronto-parietal suture; frontal region broad; zygomatica slightly spreading posteriorly, the squamosal arms not strongly bowed outward; palate narrow; audital bullae large and much inflated anteriorly.

*Measurements.*—Type: Total length, 963 mm.; tail vertebrae, 440; hind foot, 131.5. *Skull* (type): Greatest length, 99.6; condylobasal length, 95.6; zygomatic breadth, 62.8; interorbital breadth, 18.5; length of nasals (median line), 17.6; greatest breadth of nasals, 13; intertemporal breadth of braincase, 34; breadth between tips of post-orbital processes, 51.5; length of palate, 38.5; length of upper incisive tooth row, 12.2; alveolar length (outer side) of upper carnassial, 11.6.

*Remarks.*—This tiger cat is provisionally referred to the little known *F. pardinoides* group. In size it seems nearer to the *F. wiedii* group, but it lacks the reversed pelage of nape commonly ascribed to that group. Moreover, the skull is more elongated than in the available Mexican and Brazilian specimens used for comparison and assumed to represent the *F. wiedii* group. It may be similar

to *F. pardinoidea oncilla* Thomas, from Volcan de Irazu, Costa Rica, but the type of the latter without skull is described as a much smaller animal with clay colored under parts. No comparison with the forms of *Felis pajeros* seems necessary.

*Specimens examined*.—One, the type.

#### AOTUS ZONALIS, new species

*Type* from Gatun (altitude 100 feet), Canal Zone, Panama, No. 171231, skin and skull, female adult, U. S. National Museum (Biological Survey Collection); collected by E. A. Goldman, April 29, 1911. Original number 21101.

*General characters*.—Resembling *A. griseimembra*, but general color more buffy, less grayish; skull broader and differing in numerous details; dentition heavier.

*Color*.—General shade of upper parts, limbs and upper base of tail near wood brown (Ridgway, 1912) with a buffy suffusion, this color more or less heavily overlaid with russet and black along median line of back; head marked with narrow black lateral lines converging to a point on back of neck, and a black median frontal line extending from between eyes to crown; white spots above and below eyes; sides of neck grayish in some specimens; under parts light ochraceous-buff; feet blackish; proximal third of under side of tail usually stained with chestnut, the distal two-thirds black all round.

*Skull*.—Similar in general size to that of *A. griseimembra*, but broader, the greater breadth most noticeable in the braincase; interorbital region more depressed, materially altering the facial angle; frontals less extended posteriorly between parietals; parietals joined by a longer suture owing to lesser posterior development of frontals; supraoccipital reaching farther upward in a wedge-shaped extension between parietals; zygomatic portion of jugal heavier; audital bullae less inflated in front of meatus; mandible broader and heavier, the angle more everted; molariform teeth heavier.

*Measurements*.—Type: Total length, 683 mm.; tail vertebrae, 400; hind foot, 90. Average of two adult female topotypes: 637 (620-654); 357 (325-390); 85.5 (83-88). An adult male from Boca de Cupe: 670; 360; 90. *Skull* (type): Greatest length, 60.9; condylobasal length, 47.2; zygomatic breadth, 37.5; breadth between outer sides of orbits, 43.3; postorbital breadth, 31.5; mastoid breadth, 33.8; interorbital breadth, 5.2; palatal length, 17.5; maxillary tooth row, 18.3.

*Remarks.*—This species, the only known nocturnal monkey of Panama, closely resembles *A. griseimembra* of the Santa Marta region of Colombia in external appearance, the principal difference being a more general buffy suffusion of the body and limbs. The skull, however, differs in many important respects and the larger molariform teeth of the Panama animal would alone serve as a distinguishing character.

*Specimens examined.*—Total number, 10, from localities as follows:

Canal Zone: Gatun (type locality), 4.

Panama: Cana, 3; Boca de Cupe, 3.

# SMITHSONIAN PHYSICAL TABLES

*SIXTH REVISED EDITION*

PREPARED BY  
FREDERICK E. FOWLE  
AID, SMITHSONIAN ASTROPHYSICAL OBSERVATORY

(PUBLICATION 2269)

CITY OF WASHINGTON  
PUBLISHED BY THE SMITHSONIAN INSTITUTION

1914

## ADVERTISEMENT.

In connection with the system of meteorological observations established by the Smithsonian Institution about 1850, a series of meteorological tables was compiled by Dr. Arnold Guyot, at the request of Secretary Henry, and the first edition was published in 1852. Though primarily designed for meteorological observers reporting to the Smithsonian Institution, the tables were so widely used by physicists that it seemed desirable to recast the work entirely. It was decided to publish three sets of tables, each representative of the latest knowledge in its field, and independent of one another, but forming a homogeneous series. The first of the new series, Meteorological Tables, was published in 1893, the second, Geographical Tables, in 1894, and the third, Physical Tables, in 1896. In 1909 yet another volume was added, so that the series now comprises: Smithsonian Meteorological Tables, Smithsonian Geographical Tables, Smithsonian Physical Tables, and Smithsonian Mathematical Tables.

The fourteen years which had elapsed in 1910 since the publication of the first edition of the Physical Tables, prepared by Professor Thomas Gray, had brought such changes in the material upon which the tables must be based that it became necessary to make a radical revision for the 5th revised edition issued in 1910. That revision has been still further continued for the present sixth edition.

CHARLES D. WALCOTT,  
*Secretary of the Smithsonian Institution.*

*June, 1914.*

## PREFACE TO THE 5TH REVISED EDITION.

The present Smithsonian Physical Tables are the outcome of a radical revision of the set of tables compiled by Professor Thomas Gray in 1896. Recent data and many new tables have been added for which the references to the sources have been made more complete; and several mathematical tables have been added, — some of them especially computed for this work. The inclusion of these mathematical tables seems warranted by the demand for them. In order to preserve a uniform change of argument and to facilitate comparison, many of the numbers given in some tables have been obtained by interpolation in the data actually given in the papers quoted.

Our gratitude is expressed for many suggestions and for help in the improvement of the present edition: to the U. S. Bureau of Standards for the revision of the electrical, magnetic, and metrological tables and other suggestions; to the U. S. Coast and Geodetic Survey for the revision of the magnetic and geodetic tables; to the U. S. Geological Survey for various data; to Mr. Van Orstrand for several of the mathematical tables; to Mr. Wead for the data on the musical scales; to Mr. Sosman for the new physical-chemistry data; to Messrs. Abbot, Becker, Lanza, Rosa, and Wood; to the U. S. Bureau of Forestry and to others. We are also under obligation to the authors and publishers of Landolt-Börnstein-Meyerhoffer's *Physikalisch-chemische Tabellen* (1905) and B. O. Peirce's *Mathematical Tables* for the use of certain tables.

It is hardly possible that any series of tables involving so much transcribing, interpolation, and calculation should be entirely free from errors, and the Smithsonian Institution will be grateful, not only for notice of whatever errors may be found, but also for suggestions as to other changes which may seem advisable for later editions.

F. E. FOWLE.

ASTROPHYSICAL OBSERVATORY  
OF THE SMITHSONIAN INSTITUTION,  
*June, 1910*

## PREFACE TO THE 6TH REVISED EDITION.

The revision commenced for the fifth edition has been continued; a large proportion of the tables have been rechecked, typographical errors corrected, later data inserted and many new tables are added, including among others a new set of wire tables from advance sheets courteously given by the Bureau of Standards, new mathematical tables computed by Mr. Van Orstrand and those on Röntgen rays and radioactivity. The number of tables has been increased from 335 to over 400. We express our gratitude to the Bureau of Standards, to the Geophysical Laboratory, the Geological Survey, and to those who have helped through suggested improvements, new data, or by calling our attention to errors in the earlier editions.

F. E. FOWLE.

# INTRODUCTION.

---

## UNITS OF MEASUREMENT AND CONVERSION FORMULÆ.

**Units.** — The quantitative measure of anything is a number which expresses the ratio of the magnitude of the thing to the magnitude of some other thing of the same kind. In order that the number expressing the measure may be intelligible, the magnitude of the thing used for comparison must be known. This leads to the conventional choice of certain magnitudes as units of measurement, and any other magnitude is then simply expressed by a number which tells how many magnitudes equal to the unit of the same kind of magnitude it contains. For example, the distance between two places may be stated as a certain number of miles or of yards or of feet. In the first case, the mile is assumed as a known distance; in the second, the yard, and in the third, the foot. What is sought for in the statement is to convey an idea of the distance by describing it in terms of distances which are either familiar or easily referred to for comparison. Similarly quantities of matter are referred to as so many tons or pounds or grains and so forth, and intervals of time as a number of hours or minutes or seconds. Generally in ordinary affairs such statements appeal to experience; but, whether this be so or not, the statement must involve some magnitude as a fundamental quantity, and this must be of such a character that, if it is not known, it can be readily referred to. We become familiar with the length of a mile by walking over distances expressed in miles, with the length of a yard or a foot by examining a yard or a foot measure and comparing it with something easily referred to, — say our own height, the length of our foot or step, — and similarly for quantities of other kinds. This leads us to be able to form a mental picture of such magnitudes when the numbers expressing them are stated, and hence to follow intelligently descriptions of the results of scientific work. The possession of copies of the units enables us by proper comparisons to find the magnitude-numbers expressing physical quantities for ourselves. The numbers descriptive of any quantity must depend on the intrinsic magnitude of the unit in terms of which it is described. Thus a mile is 1760 yards, or 5280 feet, and hence when a mile is taken as the unit the magnitude-number for the distance is 1, when a yard is taken as the unit the magnitude-number is 1760, and when a foot is taken it is 5280. Thus, to obtain the magnitude-number for a quantity in terms of a new unit when it is already known in terms of another we have to multiply the old magnitude-number by the ratio of the intrinsic values of the old and new units; that is, by the number of the new units required to make one of the old.

**Fundamental Units of Length and Mass.**— It is desirable that as few different kinds of unit quantities as possible should be introduced into our measurements, and since it has been found possible and convenient to express a large number of physical quantities in terms of length or mass or time units and combinations of these, they have been very generally adopted as fundamental units. Two systems of such units are used in this country for scientific measurements, namely, the customary, and the French or metric, systems. Tables of conversion factors are given in the book for facilitating comparisons between quantities expressed in terms of one system with similar quantities expressed in the other. In the customary system the standard unit of length is the yard and is now defined as  $3600/3937$  meter. The unit of mass is the avoirdupois pound and is defined as  $1/2.20462$  kilogram.

The British yard is defined as the "straight line or distance (at  $62^{\circ}$  F.) between the transverse lines in the two gold plugs in the bronze bar deposited in the office of the exchequer." The British standard of mass is the pound avoirdupois and is the mass of a piece of platinum marked "P. S. 1844, 1 lb.," preserved in the exchequer office.

In the metric system the standard of length is the meter and is defined as the distance between two lines at  $0^{\circ}$  Centigrade on a platinum iridium bar deposited at the International Bureau of Weights and Measures. This bar is known as the International Prototype Meter, and its length was derived from the "mètre des Archives," which was made by Borda. Copies of the International Prototype Meter are possessed by the various governments, and are called "National Prototypes."

Borda, Delambre, Laplace, and others, acting as a committee of the French Academy, recommended that the standard unit of length should be the ten millionth part of the length, from the equator to the pole, of the meridian passing through Paris. In 1795 the French Republic passed a decree making this the legal standard of length, and an arc of the meridian extending from Dunkirk to Barcelona was measured by Delambre and Mechain for the purpose of realizing the standard. From the results of that measurement the meter bar was made by Borda. The meter is not now defined in terms of the meridian length, and hence subsequent measurements of the length of the meridian have not affected the length of the meter.

The metric standard of mass is the kilogram and is defined as the mass of a piece of platinum-iridium deposited at the International Bureau of Weights and Measures. This standard is known as the International Prototype Kilogram. Its mass is equal to that of the older standard, the "kilogramme des Archives," made by Borda and intended to have the same mass as a cubic decimeter of distilled water at the temperature of  $4^{\circ}$  C. Copies of the International Prototype Kilogram are possessed by the various governments, and as in the case of the meter standards are called National Prototypes.

Comparisons of the French and customary standards are given in tabular form in Table 2; and similarly Table 3, differing slightly, compares the British and French systems. In the metric system the decimal subdivision is used, and thus we have the decimeter, the centimeter, and the millimeter as subdivisions, and the dekameter, hektometer, and kilometer as multiples. The centimeter is most commonly used in scientific work.

**Time.** — The unit of time in both the systems here referred to is the mean solar second, or the 86,400th part of the mean solar day. The unit of time is thus founded on the average time required for the earth to make one revolution on its axis relatively to the sun as a fixed point of reference.

**Derived Units.** — Units of quantities depending on powers greater than unity of the fundamental length, mass, and time units, or on combinations of different powers of these units, are called "derived units." Thus, the unit of area and of volume are respectively the area of a square whose side is the unit of length and the volume of a cube whose edge is the unit of length. Suppose that the area of a surface is expressed in terms of the foot as fundamental unit, and we wish to find the area-number when the yard is taken as fundamental unit. The yard is 3 times as long as the foot, and therefore the area of a square whose side is a yard is  $3 \times 3$  times as great as that whose side is a foot. Thus, the surface will only make one ninth as many units of area when the yard is the unit of length as it will make when the foot is that unit. To transform, then, from the foot as old unit to the yard as new unit, we have to multiply the old area-number by  $1/9$ , or by the ratio of the magnitude of the old to that of the new unit of area. This is the same rule as that given above, but it is usually more convenient to express the transformations in terms of the fundamental units directly. In the above case, since on the method of measurement here adopted an area-number is the product of a length-number by a length-number the ratio of two units is the square of the ratio of the intrinsic values of the two units of length. Hence, if  $l$  be the ratio of the magnitude of the old to that of the new unit of length, the ratio of the corresponding units of area is  $l^2$ . Similarly the ratio of two units of volume will be  $l^3$ , and so on for other quantities.

**Dimensional Formulæ.** — It is convenient to adopt symbols for the ratios of length units, mass units, and time units, and adhere to their use throughout; and in what follows, the small letters,  $l$ ,  $m$ ,  $t$ , will be used for these ratios. These letters will always represent simple numbers, but the magnitude of the number will depend on the relative magnitudes of the units the ratios of which they represent. When the values of the numbers represented by  $l$ ,  $m$ ,  $t$  are known, and the powers of  $l$ ,  $m$ , and  $t$  involved in any particular unit are also known, the factor for transformation is at once obtained. Thus, in the above example, the value of  $l$  was  $1/3$  and the power of  $l$  involved in the expression for area is  $l^2$ ; hence, the factor for transforming from square feet to square yards is  $1/9$ . These factors

have been called by Prof. James Thomson "change ratios," which seems an appropriate term. The term "conversion factor" is perhaps more generally known, and has been used throughout this book.

**Conversion Factor.** — In order to determine the symbolic expression for the conversion factor for any physical quantity, it is sufficient to determine the degree to which the quantities length, mass, and time are involved in the quantity. Thus, a velocity is expressed by the ratio of the number representing a length to that representing an interval of time, or  $L/T$ , an acceleration by a velocity-number divided by an interval of time-number, or  $L/T^2$ , and so on, and the corresponding ratios of units must therefore enter to precisely the same degree. The factors would thus be for the above cases,  $l/t$  and  $l/t^2$ . Equations of the form above given for velocity and acceleration which show the dimensions of the quantity in terms of the fundamental units are called "dimensional equations." Thus

$$E = ML^2T^{-2}$$

is the dimensional equation for energy, and  $ML^2T^{-2}$  is the dimensional formula for energy.

In general, if we have an equation for a physical quantity

$$Q = CL^aM^bT^c,$$

where  $C$  is a constant and  $LMT$  represents length, mass, and time in terms of one set of units, and we wish to transform to another set of units in terms of which the length, mass, and time are  $L_l, M_l, T_l$ , we have to find the value of  $\frac{L_l}{L}, \frac{M_l}{M}, \frac{T_l}{T}$ , which in accordance with the convention adopted above will be  $l m t$ , or the ratios of the magnitudes of the old to those of the new units.

Thus  $L_l = Ll$ ,  $M_l = Mm$ ,  $T_l = Tt$ , and if  $Q_l$  be the new quantity-number

$$\begin{aligned} Q_l &= CL_l^a M_l^b T_l^c \\ &= CL^a M^b m^b t^c = Q l^a m^b t^c, \end{aligned}$$

or the conversion factor is  $l^a m^b t^c$ , a quantity of precisely the same form as the dimension formula  $L^a M^b T^c$ .

We now proceed to form the dimensional and conversion factor formulæ for the more commonly occurring derived units.

**1. Area.** — The unit of area is the square the side of which is measured by the unit of length. The area of a surface is therefore expressed as

$$S = CL^2,$$

where  $C$  is a constant depending on the shape of the boundary of the surface and  $L$  a linear dimension. For example, if the surface be square and  $L$  be the length of a side  $C$  is unity. If the boundary be a circle and  $L$  be a diameter  $C = \pi/4$ , and so on. The dimensional formula is thus  $L^2$ , and the conversion factor  $l^2$ .

**2. Volume.** — The unit of volume is the volume of a cube the edge of which is measured by the unit of length. The volume of a body is therefore expressed as

$$V = CL^3,$$

where as before  $C$  is a constant depending on the shape of the boundary. The dimensional formula is  $L^3$  and the conversion factor  $l^3$ .

3. **Density.** — The density of a substance is the quantity of matter in the unit of volume. The dimension formula is therefore  $M/V$  or  $ML^{-3}$ , and conversion factor  $ml^{-3}$ .

*Example.* — The density of a body is 150 in pounds per cubic foot: required the density in grains per cubic inch.

Here  $m$  is the number of grains in a pound = 7000, and  $l$  is the number of inches in a foot = 12;  $\therefore ml^{-3} = 7000/12^3 = 4.051$ . Hence the density is  $150 \times 4.051 = 607.6$  in grains per cubic inch.

NOTE. — The specific gravity of a body is the ratio of its density to the density of a standard substance. The dimension formula and conversion factor are therefore both unity.

4. **Velocity.** — The velocity of a body at any instant is given by the equation  $v = \frac{dL}{dT}$ , or velocity is the ratio of a length-number to a time-number. The dimension formula is  $LT^{-1}$ , and the conversion factor  $lt^{-1}$ .

*Example.* — A train has a velocity of 60 miles an hour: what is its velocity in feet per second?

Here  $l = 5280$  and  $t = 3600$ ;  $\therefore lt^{-1} = \frac{5280}{3600} = \frac{44}{30} = 1.467$ . Hence the velocity =  $60 \times 1.467 = 88.0$  in feet per second.

5. **Angle.** — An angle is measured by the ratio of the length of an arc to the length of the radius of the arc. The dimension formula and the conversion factor are therefore both unity.

6. **Angular Velocity.** — Angular velocity is the ratio of the magnitude of the angle described in an interval of time to the length of the interval. The dimension formula is therefore  $T^{-1}$ , and the conversion factor is  $t^{-1}$ .

7. **Linear Acceleration.** — Acceleration is the rate of change of velocity or  $a = \frac{dv}{dt}$ . The dimension formula is therefore  $VT^{-1}$  or  $LT^{-2}$ , and the conversion factor is  $lt^{-2}$ .

*Example.* — A body acquires velocity at a uniform rate, and at the end of one minute is moving at the rate of 20 kilometers per hour: what is the acceleration in centimeters per second per second?

Since the velocity gained was 20 kilometers per hour in one minute, the acceleration was 1200 kilometers per hour per hour.

Here  $l = 100\ 000$  and  $t = 3600$ ;  $\therefore lt^{-2} = 100\ 000/3600^2 = .00771$ , and therefore acceleration =  $.00771 \times 1200 = 9.26$  centimeters per second.

8. **Angular Acceleration.** — Angular acceleration is rate of change of angu-

lar velocity. The dimensional formula is thus  $\frac{\text{angular velocity}}{T}$  or  $T^{-2}$ , and the conversion factor  $t^{-2}$ .

9. **Solid Angle.** — A solid angle is measured by the ratio of the surface of the portion of a sphere enclosed by the conical surface forming the angle to the square of radius of the spherical surface, the centre of the sphere being at the vertex of the cone. The dimensional formula is therefore  $\frac{\text{area}}{L^2}$  or 1, and hence the conversion factor is also 1.

10. **Curvature.** — Curvature is measured by the rate of change of direction of the curve with reference to distance measured along the curve as independent variable. The dimension formula is therefore  $\frac{\text{angle}}{\text{length}}$  or  $L^{-1}$ , and the conversion factor is  $l^{-1}$ .

11. **Tortuosity.** — Tortuosity is measured by the rate of rotation of the tangent plane round the tangent to the curve of reference when length along the curve is independent variable. The dimension formula is therefore  $\frac{\text{angle}}{\text{length}}$  or  $L^{-1}$ , and the conversion factor is  $l^{-1}$ .

12. **Specific Curvature of a Surface.** — This was defined by Gauss to be, at any point of the surface, the ratio of the solid angle enclosed by a surface formed by moving a normal to the surface round the periphery of a small area containing the point, to the magnitude of the area. The dimensional formula is therefore  $\frac{\text{solid angle}}{\text{surface}}$  or  $L^{-2}$ , and the conversion factor is thus  $l^{-2}$ .

13. **Momentum.** — This is quantity of motion in the Newtonian sense, and is, at any instant, measured by the product of the mass-number and the velocity-number for the body.

Thus the dimension formula is  $MV$  or  $MLT^{-1}$ , and the conversion factor  $mlt^{-1}$ .

*Example.* — A mass of 10 pounds is moving with a velocity of 30 feet per second: what is its momentum when the centimeter, the gram, and the second are fundamental units?

Here  $m = 453.59$ ,  $l = 30.48$ , and  $t = 1$ ;  $\therefore mlt^{-1} = 453.59 \times 30.48 = 13825$ . The momentum is thus  $13825 \times 10 \times 30 = 4147500$ .

14. **Moment of Momentum.** — The moment of momentum of a body with reference to a point is the product of its momentum-number and the number expressing the distance of its line of motion from the point. The dimensional formula is thus  $ML^2T^{-1}$ , and hence the conversion factor is  $ml^2t^{-1}$ .

15. **Moment of Inertia.** — The moment of inertia of a body round any axis is expressed by the formula  $\Sigma mr^2$ , where  $m$  is the mass of any particle of the body

and  $r$  its distance from the axis. The dimension formula for the sum is clearly the same as for each element, and hence is  $ML^2$ . The conversion factor is therefore  $ml^2$ .

**16. Angular Momentum.** — The angular momentum of a body round any axis is the product of the numbers expressing the moment of inertia and the angular velocity of the body. The dimensional formula and the conversion factor are therefore the same as for moment of momentum given above.

**17. Force.** — A force is measured by the rate of change of momentum it is capable of producing. The dimension formulæ for force and “time rate of change of momentum” are therefore the same, and are expressed by the ratio of momentum-number to time-number or  $MLT^{-2}$ . The conversion factor is thus  $mlt^{-2}$ .

NOTE. — When mass is expressed in pounds, length in feet, and time in seconds, the unit force is called the poundal. When grams, centimeters, and seconds are the corresponding units the unit of force is called the dyne.

*Example.* Find the number of dynes in 25 poundals.

Here  $m = 453.59$ ,  $l = 30.48$ , and  $t = 1$ ;  $\therefore mlt^{-2} = 453.59 \times 30.48 = 13825$  nearly. The number of dynes is thus  $13825 \times 25 = 345625$  approximately.

**18. Moment of a Couple, Torque, or Twisting Motive.** — These are different names for a quantity which can be expressed as the product of two numbers representing a force and a length. The dimension formula is therefore  $FL$  or  $ML^2T^{-2}$ , and the conversion factor is  $ml^2t^{-2}$ .

**19. Intensity of a Stress.** — The intensity of a stress is the ratio of the number expressing the total stress to the number expressing the area over which the stress is distributed. The dimensional formula is thus  $FL^{-2}$  or  $ML^{-1}T^{-2}$ , and the conversion factor is  $ml^{-1}t^{-2}$ .

**20. Intensity of Attraction, or “Force at a Point.”** — This is the force of attraction per unit mass on a body placed at the point, and the dimensional formula is therefore  $FM^{-1}$  or  $LT^{-2}$ , the same as acceleration. The conversion factors for acceleration therefore apply.

**21. Absolute Force of a Centre of Attraction, or “Strength of a Centre.”** — This is the intensity of force at unit distance from the centre, and is therefore the force per unit mass at any point multiplied by the square of the distance from the centre. The dimensional formula thus becomes  $FL^2M^{-1}$  or  $L^3T^{-2}$ . The conversion factor is therefore  $l^3t^{-2}$ .

**22. Modulus of Elasticity.** — A modulus of elasticity is the ratio of stress intensity to percentage strain. The dimension of percentage strain is a length divided by a length, and is therefore unity. Hence, the dimensional formula of a modulus of elasticity is the same as that of stress intensity, or  $ML^{-1}T^{-2}$ , and the conversion factor is thus also  $ml^{-1}t^{-2}$ .

23. **Work and Energy.** — When the point of application of a force, acting on a body, moves in the direction of the force, work is done by the force, and the amount is measured by the product of the force and displacement numbers. The dimensional formula is therefore  $FL$  or  $ML^2T^{-2}$ .

The work done by the force either produces a change in the velocity of the body or a change of shape or configuration of the body, or both. In the first case it produces a change of kinetic energy, in the second a change of potential energy. The dimension formulæ of energy and work, representing quantities of the same kind, are identical, and the conversion factor for both is  $ml^2t^{-2}$ .

24. **Resilience.** — This is the work done per unit volume of a body in distorting it to the elastic limit or in producing rupture. The dimension formula is therefore  $ML^2T^{-2}L^{-3}$  or  $ML^{-1}T^{-2}$ , and the conversion factor  $ml^{-1}t^{-2}$ .

25. **Power, or Activity.** — Power — or, as it is now very commonly called, activity — is defined as the time rate of doing work, or if  $W$  represent work and  $P$  power  $P = \frac{dW}{dt}$ . The dimensional formula is therefore  $WT^{-1}$  or  $ML^2T^{-3}$ , and the conversion factor  $ml^2t^{-3}$ , or for problems in gravitation units more conveniently  $ftt^{-1}$ , where  $f$  stands for the force factor.

*Examples.* (a) Find the number of gram centimeters in one foot pound.

Here the units of force are the attraction of the earth on the pound\* and the gram of matter, and the conversion factor is  $fl$ , where  $f$  is 453.59 and  $l$  is 30.48.

Hence the number is  $453.59 \times 30.48 = 13825$ .

(b) Find the number of foot poundals in 1 000 000 centimeter dynes.

Here  $m = 1/453.59$ ,  $l = 1/30.48$ , and  $t = 1$ ;  $\therefore ml^2t^{-2} = 1/453.59 \times 30.48^2$ , and  $10^6 ml^2t^{-2} = 10^6/453.59 \times 30.48^2 = 2.373$ .

(c) If gravity produces an acceleration of 32.2 feet per second per second, how many watts are required to make one horse-power?

One horse-power is 550 foot pounds per second, or  $550 \times 32.2 = 17710$  foot poundals per second. One watt is  $10^7$  ergs per second, that is,  $10^7$  dyne centimeters per second. The conversion factor is  $ml^2t^{-3}$ , where  $m = 453.59$ ,  $l = 30.48$ , and  $t = 1$ , and the result has to be divided by  $10^7$ , the number of dyne centimeters per second in the watt.

Hence,  $17710 ml^2t^{-3}/10^7 = 17710 \times 453.59 \times 30.48^2/10^7 = 746.3$ .

(d) How many gram centimeters per second correspond to 33000 foot pounds per minute?

The conversion factor suitable for this case is  $flt^{-1}$ , where  $f$  is 453.59,  $l$  is 30.48, and  $t$  is 60.

Hence,  $33000 ft^{-1} = 33000 \times 453.59 \times 30.48/60 = 7604000$  nearly.

\* It is important to remember that in problems like that here given the term "pound" or "gram" refers to force and not to mass.

## HEAT UNITS.

1. If heat be measured in dynamical units its dimensions are the same as those of energy, namely  $ML^2T^{-2}$ . The most common measurements, however, are made in thermal units, that is, in terms of the amount of heat required to raise the temperature of unit mass of water one degree of temperature at some stated temperature. This method of measurement involves the unit of mass and some unit of temperature; and hence, if we denote temperature-numbers by  $\Theta$  and their conversion factors by  $\theta$ , the dimensional formula and conversion factor for quantity of heat will be  $M\Theta$  and  $m\theta$  respectively. The relative amount of heat compared with water as standard substance required to raise unit mass of different substances one degree in temperature is called their specific heat, and is a simple number.

Unit volume is sometimes used instead of unit mass in the measurement of heat, the units being then called thermometric units. The dimensional formula is in that case changed by the substitution of volume for mass, and becomes  $L^3\Theta$ , and hence the conversion factor is to be calculated from the formula  $l^3\theta$ .

For other physical quantities involving heat we have:—

2. **Coefficient of Expansion.**—The coefficient of expansion of a substance is equal to the ratio of the change of length per unit length (linear), or change of volume per unit volume (voluminal) to the change of temperature. These ratios are simple numbers, and the change of temperature is inversely as the magnitude of the unit of temperature. Hence the dimensional and conversion-factor formulæ are  $\Theta^{-1}$  and  $\theta^{-1}$ .

3. **Conductivity, or Specific Conductance.**—This is the quantity of heat transmitted per unit of time per unit of surface per unit of temperature gradient. The equation for conductivity is therefore, with  $H$  as quantity of heat,

$$K = \frac{H}{\frac{\Theta}{L}L^2T}$$

and the dimensional formula  $\frac{H}{\Theta LT} = \frac{M}{LT}$ , which gives  $ml^{-1}t^{-1}$  for conversion factor.

In thermometric units the formula becomes  $L^2T^{-1}$ , which properly represents diffusivity. In dynamical units  $H$  becomes  $ML^2T^{-2}$ , and the formula changes to  $MLT^{-3}\Theta^{-1}$ . The conversion factors obtained from these are  $l^2t^{-1}$  and  $mlt^{-3}\theta^{-1}$  respectively.

4. **Thermal Capacity.** — This is the product of the number for mass and the specific heat, and hence the dimensional formula and conversion factor are simply  $M$  and  $m$ .

5. **Latent Heat.** — Latent heat is the ratio of the number representing the quantity of heat required to change the state of a body to the number representing the quantity of matter in the body. The dimensional formula is therefore  $M\Theta/M$  or  $\Theta$ , and hence the conversion factor is simply the ratio of the temperature units or  $\theta$ . In dynamical units the factor is  $l^2t^{-2}$ .\*

6. **Joule's Equivalent.** — Joule's dynamical equivalent is connected with quantity of heat by the equation

$$ML^2T^{-2} = JH \text{ or } JM\Theta.$$

This gives for the dimensional formula of  $J$  the expression  $L^2T^{-2}\Theta^{-1}$ . The conversion factor is thus represented by  $l^2t^{-2}\theta^{-1}$ . When heat is measured in dynamical units  $J$  is a simple number.

7. **Entropy.** — The entropy of a body is directly proportional to the quantity of heat it contains and inversely proportional to its temperature. The dimensional formula is thus  $M\Theta/\Theta$  or  $M$ , and the conversion factor is  $m$ . When heat is measured in dynamical units the factor is  $ml^2t^{-2}\theta^{-1}$ .

*Examples.* (a) Find the relation between the British thermal unit, the calorie, and the therm.

Neglecting the variation of the specific heat of water with temperature, or defining all the units for the same temperature of the standard substance, we have the following definitions. The *British thermal unit* is the quantity of heat required to raise the temperature of one pound of water  $1^\circ$  F. The *calorie* is the quantity of heat required to raise the temperature of one kilogramme of water  $1^\circ$  C. The *therm* is the quantity of heat required to raise the temperature of one gramme of water  $1^\circ$  C. Hence:—

(1) To find the number of calories in one British thermal unit, we have  $m = .45359$  and  $\theta = \frac{5}{9}$ ;  $\therefore m\theta = .45359 \times 5/9 = .25199$ .

(2) To find the number of therms in one calorie,  $m = 1000$  and  $\theta = 1$ ;  $\therefore m\theta = 1000$ .

It follows at once that the number of therms in one British thermal unit is  $1000 \times .25199 = 251.99$ .

(b) What is the relation between the foot grain second Fahrenheit-degree and the centimetre gramme second Centigrade-degree units of conductivity?

The number of the latter units in one of the former is given by the for-

\* It will be noticed that when  $\Theta$  is given the dimension formula  $L^2T^{-2}$  the formulæ in thermal and dynamical units are always identical. The thermometric units practically suppress mass.

mula  $ml^{-1}t^{-1}\theta^0$ , where  $m = .064799$ ,  $l = 30.48$ , and  $t = 1$ , and is therefore  $= .064799/30.48 = 2.126 \times 10^{-3}$ .

(c) Find the relation between the units stated in (b) for emissivity.

In this case the conversion formula is  $ml^{-2}t^{-1}$ , where  $ml$  and  $t$  have the same value as before. Hence the number of the latter units in the former is  $0.064799/30.48^2 = 6.975 \times 10^{-5}$ .

(d) Find the number of centimeter gram second units in the inch grain hour unit of emissivity.

Here the formula is  $ml^{-2}t^{-1}$ , where  $m = 0.064799$ ,  $l = 2.54$ , and  $t = 3600$ . Therefore the required number is  $0.064799/2.54^2 \times 3600 = 2.790 \times 10^{-5}$ .

(e) If Joule's equivalent be 776 foot pounds per pound of water per degree Fahrenheit, what will be its value in gravitation units when the metre, the kilogramme, and the degree Centigrade are units?

The conversion factor in this case is  $\frac{l^2 t^{-2} \theta^{-1}}{l t^{-2}}$  or  $l \theta^{-1}$ , where  $l = .3048$  and  $\theta^{-1} = 1.8$ ;  $\therefore 776 \times .3048 \times 1.8 = 425.7$ .

(f) If Joule's equivalent be 24832 foot poundals when the degree Fahrenheit is unit of temperature, what will be its value when kilogram meter second and degree-Centigrade units are used?

The conversion factor is  $l^2 t^{-2} \theta^{-1}$ , where  $l = .3048$ ,  $t = 1$ , and  $\theta^{-1} = 1.8$ ;  $\therefore 24832 \times l^2 t^{-2} \theta^{-1} = 24832 \times .3048^2 \times 1.8 = 4152.5$ .

In gravitation units this would give  $4152.5/9.81 = 423.3$ .

## ELECTRIC AND MAGNETIC UNITS.

There are two systems of these units, the electrostatic and the electromagnetic systems, which differ from each other because of the different fundamental suppositions on which they are based. In the electrostatic system the repulsive force between two quantities of static electricity is made the basis. This connects force, quantity of electricity, and length by the equation  $f = a \frac{qq_1}{l^2}$ , where  $f$  is force,  $a$  a quantity depending on the units employed and on the nature of the medium,  $q$  and  $q_1$  quantities of electricity, and  $l$  the distance between  $q$  and  $q_1$ . The magnitude of the force  $f$  for any particular values of  $q$ ,  $q_1$  and  $l$  depends on a property of the medium across which the force takes place called its inductive capacity. The inductive capacity of air has generally been assumed as unity, and the inductive capacity of other media expressed as a number representing the ratio of the inductive capacity of the medium to that of air. These numbers are known as the specific inductive capacities of the media. According to the ordinary assumption, then, of air as the standard medium, we obtain unit quantity of electricity when in the above equation  $q = q_1$ , and  $f$ ,  $a$ , and  $l$  are each unity. A formal definition is given below.

In the electromagnetic system the repulsion between two magnetic poles or

quantities of magnetism is taken as the basis. In this system the quantities force, quantity of magnetism, and length are connected by an equation of the form

$$f = a \frac{mm_1}{l^2},$$

where  $m$  and  $m_1$  are in this case quantities of magnetism, and the other symbols have the same meaning as before. In this case it has been usual to assume the magnetic inductive capacity of air to be unity, and to express the magnetic inductive capacity of other media as a simple number representing the ratio of the inductive capacity of the medium to that of air. These numbers, by analogy with specific inductive capacity for electricity, might be called specific inductive capacities for magnetism. They are usually called permeabilities. (*Vide* Thomson, "Papers on Electrostatics and Magnetism," p. 484.) In this case, also, like that for electricity, the unit quantity of magnetism is obtained by making  $m = m_1$ , and  $f$ ,  $a$ , and  $l$  each unity.

In both these cases the intrinsic inductive capacity of the standard medium is suppressed, and hence also that of all other media. Whether this be done or not, direct experiment has to be resorted to for the determination of the absolute values of the units and the relations of the units in the one system to those in the other. The character of this relation can be directly inferred from the dimensional formulæ of the different quantities, but these can give no information as to the relative absolute values of the units in the two systems. Prof. Rücker has suggested (*Phil. Mag.* vol. 27) the advisability of at least indicating the existence of the suppressed properties by putting symbols for them in the dimensional formulæ. This has the advantage of showing how the magnitudes of the different units would be affected by a change in the standard medium, or by making the standard medium different for the two systems. In accordance with this idea, the symbols  $K$  and  $P$  have been introduced into the formulæ given below to represent inductive capacity in the electrostatic and the electromagnetic systems respectively. In the conversion formulæ  $k$  and  $p$  are the ordinary specific inductive capacities and permeabilities of the media when air is taken as the standard, or generally those with reference to the first medium taken as standard. The ordinary formulæ may be obtained by putting  $K$  and  $P$  equal to unity.

---

## ELECTROSTATIC UNITS.

**1. Quantity of Electricity.** — The unit quantity of electricity is defined as that quantity which if concentrated at a point and placed at unit distance from an equal and similarly concentrated quantity repels it, or is repelled by it, with unit force. The medium or dielectric is usually taken as air, and the other units in accordance with the centimeter gram second system.

In this case we have the force of repulsion proportional directly to the square of the quantity of electricity and inversely to the square of the distance between the quantities and to the inductive capacity. The dimensional formula is therefore the same as that for [force  $\times$  length<sup>2</sup>  $\times$  inductive capacity]<sup>3</sup> or  $M^3L^3T^{-1}K^3$ , and the conversion factor is  $m^3M^{-1}t^{-1}k^3$ .

2. **Electric Surface Density and Electric Displacement.** — The density of an electric distribution at any point on a surface is measured by the quantity per unit of area, and the electric displacement at any point in a dielectric is measured by the quantity displaced per unit of area. These quantities have therefore the same dimensional formulæ, namely, the ratio of the formulæ for quantity of electricity and for area or  $M^{\frac{1}{2}}L^{-1}T^{-1}K^{\frac{1}{2}}$ , and the conversion factor  $m^{\frac{1}{2}}t^{-1}k^{\frac{1}{2}}$ .

3. **Electric Force at a Point, or Intensity of Electric Field.** — This is measured by the ratio of the magnitude of the force on a quantity of electricity at a point to the magnitude of the quantity of electricity. The dimensional formula is therefore the ratio of the formulæ for force and electric quantity, or

$$\frac{MLT^{-2}}{M^{\frac{1}{2}}L^{\frac{3}{2}}T^{-1}K^{\frac{1}{2}}} = M^{\frac{1}{2}}L^{-1}T^{-1}K^{-\frac{1}{2}},$$

which gives the conversion factor  $m^{\frac{1}{2}}t^{-1}k^{-\frac{1}{2}}$ .

4. **Electric Potential and Electromotive Force.** — Change of potential is proportional to the work done per unit of electricity in producing the change. The dimensional formula is therefore the ratio of the formulæ for work and electric quantity, or

$$\frac{ML^2T^{-2}}{M^{\frac{1}{2}}L^{\frac{3}{2}}T^{-1}K^{\frac{1}{2}}} = M^{\frac{1}{2}}L^{\frac{1}{2}}T^{-1}K^{-\frac{1}{2}},$$

which gives the conversion factor  $m^{\frac{1}{2}}t^{-1}k^{-\frac{1}{2}}$ .

5. **Capacity of a Conductor.** — The capacity of an insulated conductor is proportional to the ratio of the numbers representing the quantity of electricity in a charge and the potential of the charge. The dimensional formula is thus the ratio of the two formulæ for electric quantity and potential, or

$$\frac{M^{\frac{1}{2}}L^{\frac{3}{2}}T^{-1}K^{\frac{1}{2}}}{M^{\frac{1}{2}}L^{\frac{1}{2}}T^{-1}K^{-\frac{1}{2}}} = LK,$$

which gives  $Lk$  for conversion factor. When  $K$  is taken as unity, as in the ordinary units, the capacity of an insulated conductor is simply a length.

6. **Specific Inductive Capacity.** — This is the ratio of the inductive capacity of the substance to that of a standard substance, and hence the dimensional formula is  $K/K$  or  $\epsilon$ .\*

7. **Electric Current.** — Current is quantity flowing past a point per unit of time. The dimensional formula is thus the ratio of the formulæ for electric quantity and for time, or

$$\frac{M^{\frac{1}{2}}L^{\frac{3}{2}}T^{-1}K^{\frac{1}{2}}}{T} = M^{\frac{1}{2}}L^{\frac{3}{2}}T^{-2}K^{\frac{1}{2}},$$

and the conversion factor  $m^{\frac{1}{2}}t^{-2}k^{\frac{1}{2}}$ .

\* According to the ordinary definition referred to air as standard medium, the specific inductive capacity of a substance is  $K$ , or is identical in dimensions with what is here taken as inductive capacity. Hence in that case the conversion factor must be taken as  $\epsilon$  on the electrostatic and as  $t^{-2}k^2$  on the electromagnetic system.

8. **Conductivity, or Specific \* Conductance.**— This, like the corresponding term for heat, is quantity per unit area per unit potential gradient per unit of time. The dimensional formula is therefore

$$\frac{M^{\frac{1}{2}}L^{\frac{3}{2}}T^{-1}K^{\frac{1}{2}}}{L^2 \frac{M^{\frac{1}{2}}L^{\frac{3}{2}}T^{-1}K^{-\frac{1}{2}}}{L} T} = T^{-1}K, \text{ or } \frac{\text{electric quantity}}{\text{area} \times \text{potential gradient} \times \text{time}}.$$

The conversion factor is  $t^{-1}k$ .

9. **Specific \* Resistance.**— This is the reciprocal of conductivity as above defined, and hence the dimensional formula and conversion factor are respectively  $TK^{-1}$  and  $tk^{-1}$ .

10. **Conductance.**— The conductance of any part of an electric circuit, not containing a source of electromotive force, is the ratio of the numbers representing the current flowing through it and the difference of potential between its ends. The dimensional formula is thus the ratio of the formulæ for current and potential, or

$$\frac{M^{\frac{1}{2}}L^{\frac{3}{2}}T^{-2}K^{\frac{1}{2}}}{M^{\frac{1}{2}}L^{\frac{3}{2}}T^{-1}K^{-\frac{1}{2}}} = LT^{-1}K,$$

from which we get the conversion factor  $lt^{-1}k$ .

11. **Resistance.**— This is the reciprocal of conductance, and therefore the dimensional formula and the conversion factor are respectively  $L^{-1}TK^{-1}$  and  $l^{-1}tk^{-1}$ .

---

#### EXAMPLES OF CONVERSION IN ELECTROSTATIC UNITS.

(a) Find the factor for converting quantity of electricity expressed in foot grain second units to the same expressed in c. g. s. units.

By (1) the formula is  $m^{\frac{1}{2}}l^{\frac{3}{2}}t^{-1}k^{\frac{1}{2}}$ , in which in this case  $m = 0.0648$ ,  $l = 30.48$ ,  $t = 1$ , and  $k = 1$ ;  $\therefore$  the factor is  $0.0648^{\frac{1}{2}} \times 30.48^{\frac{3}{2}} = 4.2836$ .

(b) Find the factor required to convert electric potential from millimeter milligram second units to c. g. s. units.

By (4) the formula is  $m^{\frac{1}{2}}l^{\frac{3}{2}}t^{-1}k^{-\frac{1}{2}}$ , and in this case  $m = 0.001$ ,  $l = 0.1$ ,  $t = 1$ , and  $k = 1$ ;  $\therefore$  the factor  $= 0.001^{\frac{1}{2}} \times 0.1^{\frac{3}{2}} = 0.01$ .

(c) Find the factor required to convert from foot grain second and specific inductive capacity 6 units to c. g. s. units.

By (5) the formula is  $lk$ , and in this case  $l = 30.48$  and  $k = 6$ ;  $\therefore$  the factor  $= 30.48 \times 6 = 182.88$ .

\* The term "specific," as used here and in 9, refers conductance and resistance to that between the ends of a bar of unit section and unit length, and hence is different from the same term in specific heat, specific inductivity, capacity, etc., which refer to a standard substance.

## ELECTROMAGNETIC UNITS.

As stated above, these units bear the same relation to unit quantity of magnetism that the electric units do to quantity of electricity. Thus, when inductive capacity is suppressed, the dimensional formula for magnetic quantity on this system is the same as that for electric quantity on the electrostatic system. All quantities in this system which only differ from corresponding quantities defined above by the substitution of magnetic for electric quantity may have their dimensional formulæ derived from those of the corresponding quantity by substituting  $P$  for  $K$ .

**1. Magnetic Pole, or Quantity of Magnetism.** — Two unit quantities of magnetism concentrated at points unit distance apart repel each other with unit force. The dimensional formula is thus the same as for [force  $\times$  length<sup>2</sup>  $\times$  inductive capacity]<sup>½</sup> or  $M^{\frac{1}{2}}L^{\frac{3}{2}}T^{-1}P^{\frac{1}{2}}$ , and the conversion factor is  $m^{\frac{1}{2}}l^{\frac{3}{2}}t^{-1}p^{\frac{1}{2}}$ .

**2. Density of Surface Distribution of Magnetism.** — This is measured by quantity of magnetism per unit area, and the dimension formula is therefore the ratio of the expressions for magnetic quantity and for area, or  $M^{\frac{1}{2}}L^{-\frac{1}{2}}T^{-1}P^{\frac{1}{2}}$ , which gives the conversion factor  $m^{\frac{1}{2}}l^{-\frac{1}{2}}t^{-1}p^{\frac{1}{2}}$ .

**3. Magnetic Force at a Point, or Intensity of Magnetic Field.** — The number for this is the ratio of the numbers representing the magnitudes of the force on a magnetic pole placed at the point and the magnitude of the magnetic pole.

The dimensional formula is therefore the ratio of the expressions for force and magnetic quantity, or

$$\frac{MLT^{-2}}{M^{\frac{1}{2}}L^{\frac{3}{2}}T^{-1}P^{\frac{1}{2}}} = M^{\frac{1}{2}}L^{-1}T^{-1}P^{-\frac{1}{2}},$$

and the conversion factor  $m^{\frac{1}{2}}l^{-1}t^{-1}p^{-\frac{1}{2}}$ .

**4. Magnetic Potential.** — The magnetic potential at a point is measured by the work which is required to bring unit quantity of positive magnetism from zero potential to the point. The dimensional formula is thus the ratio of the formula for work and magnetic quantity, or

$$\frac{ML^2T^{-2}}{M^{\frac{1}{2}}L^{\frac{3}{2}}T^{-1}P^{\frac{1}{2}}} = M^{\frac{1}{2}}L^{\frac{1}{2}}T^{-1}P^{-\frac{1}{2}},$$

which gives the conversion factor  $m^{\frac{1}{2}}l^{\frac{1}{2}}t^{-1}p^{-\frac{1}{2}}$ .

**5. Magnetic Moment.** — This is the product of the numbers for pole strength and length of a magnet. The dimensional formula is therefore the product of the formulæ for magnetic quantity and length, or  $M^{\frac{1}{2}}L^{\frac{5}{2}}T^{-1}P^{\frac{1}{2}}$ , and the conversion factor  $m^{\frac{1}{2}}l^{\frac{5}{2}}t^{-1}p^{\frac{1}{2}}$ .

**6. Intensity of Magnetization.** — The intensity of magnetization of any portion of a magnetized body is the ratio of the numbers representing the magni-

tude of the magnetic moment of that portion and its volume. The dimensional formula is therefore the ratio of the formulæ for magnetic moment and volume, or

$$\frac{M^1 L^3 T^{-1} P^1}{L^3} = M^1 L^{-1} T^{-1} P^1.$$

The conversion factor is therefore  $m^1 l^{-1} t^{-1} p^1$ .

7. **Magnetic Permeability,\* or Specific Magnetic Inductive Capacity.** — This is the analogue in magnetism to specific inductive capacity in electricity. It is the ratio of the magnetic induction in the substance to the magnetic induction in the field which produces the magnetization, and therefore its dimensional formula and conversion factor are unity.

8. **Magnetic Susceptibility.** — This is the ratio of the numbers which represent the values of the intensity of magnetization produced and the intensity of the magnetic field producing it. The dimensional formula is therefore the ratio of the formulæ for intensity of magnetization and magnetic field or

$$\frac{M^1 L^{-1} T^{-1} P^1}{M^1 L^{-1} T^{-1} P^{-1}} \text{ or } P.$$

The conversion factor is therefore  $p$ , and both the dimensional formula and conversion factor are unity in the ordinary system.

9. **Current Strength.** — A current of strength  $c$  flowing round a circle of radius  $r$  produces a magnetic field at the centre of intensity  $2\pi c/r$ . The dimensional formula is therefore the product of the formulæ for magnetic field intensity and length, or  $M^1 L^1 T^{-1} P^{-1}$ , which gives the conversion factor  $m^1 l^1 t^{-1} p^{-1}$ .

10. **Current Density, or Strength of Current at a Point.** — This is the ratio of the numbers for current strength and area. The dimensional formula and the conversion factor are therefore  $M^1 L^{-2} T^{-1} P^{-1}$  and  $m^1 l^{-2} t^{-1} p^{-1}$ .

11. **Quantity of Electricity.** — This is the product of the numbers for current and time. The dimensional formula is therefore  $M^1 L^1 T^{-1} P^{-1} \times T = M^1 L^1 P^{-1}$ , and the conversion factor  $m^1 l^1 p^{-1}$ .

12. **Electric Potential, or Electromotive Force.** — As in the electrostatic system, this is the ratio of the numbers for work and quantity of electricity. The dimensional formula is therefore

$$\frac{ML^2 T^{-2}}{M^1 L^1 P^{-1}} = M^1 L^1 T^{-2} P^1,$$

and the conversion factor  $m^1 l^1 t^{-2} p^1$ .

\* Permeability, as ordinarily taken with the standard medium as unity, has the same dimension formula and conversion factor as that which is here taken as magnetic inductive capacity. Hence for ordinary transformations the conversion factor should be taken as 1 in the electromagnetic and  $J^{-2} l^2$  in the electrostatic systems.

13. **Electrostatic Capacity.** — This is the ratio of the numbers for quantity of electricity and difference of potential. The dimensional formula is therefore

$$\frac{M^{\frac{1}{2}}L^{\frac{1}{2}}P^{-\frac{1}{2}}}{M^{\frac{1}{2}}L^{\frac{3}{2}}T^{-2}P^{\frac{1}{2}}} = L^{-1}T^2P^{-1},$$

and the conversion factor  $l^{-1}t^2\phi^{-1}$ .

14. **Resistance of a Conductor.** — The resistance of a conductor or electrode is the ratio of the numbers for difference of potential between its ends and the constant current it is capable of producing. The dimensional formula is therefore the ratio of those for potential and current or

$$\frac{M^{\frac{1}{2}}L^{\frac{3}{2}}T^{-2}P^{\frac{1}{2}}}{M^{\frac{1}{2}}L^{\frac{3}{2}}T^{-1}P^{-\frac{1}{2}}} = LT^{-1}P.$$

The conversion factor thus becomes  $lt^{-1}\phi$ , and in the ordinary system resistance has the same conversion factor as velocity.

15. **Conductance.** — This is the reciprocal of resistance, and hence the dimensional formula and conversion factor are respectively  $L^{-1}TP^{-1}$  and  $l^{-1}t\phi^{-1}$ .

16. **Conductivity, or Specific Conductance.** — This is quantity of electricity transmitted per unit of area per unit of potential gradient per unit of time. The dimensional formula is therefore derived from those of the quantities mentioned as follows: —

$$\frac{M^{\frac{1}{2}}L^{\frac{1}{2}}P^{-\frac{1}{2}}}{\frac{L^2M^{\frac{1}{2}}L^{\frac{3}{2}}T^{-2}P^{\frac{1}{2}}}{L}T} = L^{-2}TP^{-1}.$$

The conversion factor is therefore  $l^{-2}t\phi^{-1}$ .

17. **Specific Resistance.** — This is the reciprocal of conductivity as defined in 16, and hence the dimensional formula and conversion factor are respectively  $L^2T^{-1}P$  and  $l^2t^{-1}\phi$ .

18. **Coefficient of Self-Induction, or Inductance, or Electro-kinetic Inertia.** — These are for any circuit the electromotive force produced in it by unit rate of variation of the current through it. The dimensional formula is therefore the product of the formulæ for electromotive force and time divided by that for current or

$$\frac{M^{\frac{1}{2}}L^{\frac{3}{2}}T^{-2}P^{\frac{1}{2}}}{M^{\frac{1}{2}}L^{\frac{3}{2}}T^{-1}P^{-\frac{1}{2}}} \times T = LP.$$

The conversion factor is therefore  $l\phi$ , and in the ordinary system is the same as that for length.

19. **Coefficient of Mutual Induction.** — The mutual induction of two circuits is the electromotive force produced in one per unit rate of variation of the current in the other. The dimensional formula and the conversion factor are therefore the same as those for self-induction.

20. **Electro-kinetic Momentum.**—The number for this is the product of the numbers for current and for electro-kinetic inertia. The dimensional formula is therefore the product of the formulæ for these quantities, or  $M^3L^3T^{-1}P^{-1} \times LP = M^3L^3T^{-1}P^2$ , and the conversion factor is  $m^3l^3t^{-1}p^2$ .

21. **Electromotive Force at a Point.**—The number for this quantity is the ratio of the numbers for electric potential or electromotive force as given in 12, and for length. The dimensional formula is therefore  $M^3L^3T^{-2}P^2$ , and the conversion factor  $m^3l^3t^{-2}p^2$ .

22. **Vector Potential.**—This is time integral of electromotive force at a point, or the electro-kinetic momentum at a point. The dimensional formula may therefore be derived from 21 by multiplying by T, or from 20 by dividing by L. It is therefore  $M^3L^3T^{-1}P^2$ , and the conversion factor  $m^3l^3t^{-1}p^2$ .

23. **Thermoelectric Height.**—This is measured by the ratio of the numbers for electromotive force and for temperature. The dimensional formula is therefore the ratio of the formulæ for these two quantities, or  $M^3L^3T^{-2}P^2\Theta^{-1}$ , and the conversion factor  $m^3l^3t^{-2}p^2\theta^{-1}$ .

24. **Specific Heat of Electricity.**—This quantity is measured in the same way as 23, and hence has the same formulæ.

25. **Coefficient of Peltier Effect.**—This is measured by the ratio of the numbers for quantity of heat and for quantity of electricity. The dimensional formula is therefore

$$\frac{M\Theta}{M^3L^3P^{-1}} = M^2L^{-3}P^2\Theta,$$

and the conversion factor  $m^2l^{-3}p^2\theta$ .

---

#### EXAMPLES OF CONVERSION IN ELECTROMAGNETIC UNITS.

(a) Find the factor required to convert intensity of magnetic field from foot grain minute units to c. g. s. units.

By (3) the formula is  $m^3l^{-1}t^{-1}p^{-1}$ , and in this case  $m = 0.0648$ ,  $l = 30.48$ ,  $t = 60$ , and  $p = 1$ ;  $\therefore$  the factors  $= 0.0648^3 \times 30.48^{-1} \times 60^{-1} = 0.00076847$ .

Similarly to convert from foot grain second units to c. g. s. units the factor is  $0.0648^3 \times 30.48^{-1} = 0.046108$ .

(b) How many c. g. s. units of magnetic moment make one foot grain second unit of the same quantity?

By (5) the formula is  $m^3l^3t^{-1}p^2$ , and the values for this problem are  $m = 0.0648$ ,  $l = 30.48$ ,  $t = 1$ , and  $p = 1$ ;  $\therefore$  the number  $= 0.0648^3 \times 30.48^3 = 1305.6$ .

(c) If the intensity of magnetization of a steel bar be 700 in c. g. s. units, what will it be in millimeter milligram second units?

By (6) the formula is  $m^{1/2}l^{-1}p^3$ , and in this case  $m = 1000$ ,  $l = 10$ ,  $t = 1$ , and  $p = 1$ ;  $\therefore$  the intensity  $= 700 \times 1000^3 \times 10^3 = 70000$ .

(d) Find the factor required to convert current strength from c. g. s. units to earth quadrant  $10^{-11}$  gram and second units.

By (9) the formula is  $m^{1/2}l^{-1}p^{-3}$ , and the values of these quantities are here  $m = 10^{11}$ ,  $l = 10^{-9}$ ,  $t = 1$ , and  $p = 1$ ;  $\therefore$  the factor  $= 10^{13} \times 10^{-3} = 10$ .

(e) Find the factor required to convert resistance expressed in c. g. s. units into the same expressed in earth-quadrant  $10^{-11}$  gram and second units.

By (14) the formula is  $l^{-2}p$ , and for this case  $l = 10^{-9}$ ,  $t = 1$ , and  $p = 1$ ;  $\therefore$  the factor  $= 10^{-9}$ .

(f) Find the factor required to convert electromotive force from earth-quadrant  $10^{-11}$  gram and second units to c. g. s. units.

By (12) the formula is  $m^{1/2}l^{-2}p^3$ , and for this case  $m = 10^{-11}$ ,  $l = 10^9$ ,  $t = 1$ , and  $p = 1$ ;  $\therefore$  the factor  $= 10^8$ .

---

### PRACTICAL UNITS.

In practical electrical measurements the units adopted are either multiples or submultiples of the units founded on the centimeter, the gram, and the second as fundamental units, and air is taken as the standard medium, for which K and P are assumed unity. The following, quoted from the report to the Honorable the Secretary of State, under date of November 6th, 1893, by the delegates representing the United States, gives the ordinary units with their names and values as defined by the International Congress at Chicago in 1893:—

“Resolved, That the several governments represented by the delegates of this International Congress of Electricians be, and they are hereby, recommended to formally adopt as legal units of electrical measure the following: As a unit of resistance, the *international ohm*, which is based upon the ohm equal to  $10^9$  units of resistance of the C. G. S. system of electro-magnetic units, and is represented by the resistance offered to an unvarying electric current by a column of mercury at the temperature of melting ice 14.4521 grams in mass, of a constant cross-sectional area and of the length of 106.3 centimeters.

“As a unit of current, the *international ampère*, which is one tenth of the unit of current of the C. G. S. system of electro-magnetic units, and which is represented sufficiently well for practical use by the unvarying current which, when passed through a solution of nitrate of silver in water, and in accordance with accompanying specifications,\* deposits silver at the rate of 0.001118 of a gram per second.

\* “In the following specification the term ‘silver voltameter’ means the arrangement of apparatus by means of which an electric current is passed through a solution of nitrate of silver in water. The silver voltameter measures the total electrical quantity which has passed during the time of the experiment, and by noting this time the time average of the current, or, if the current has been kept constant, the current itself can be deduced.

“In employing the silver voltameter to measure currents of about one ampère, the following arrangements should be adopted:—

“As a unit of electromotive force, the *international volt*, which is the electromotive force that, steadily applied to a conductor whose resistance is one international ohm, will produce a current of one international ampère, and which is represented sufficiently well for practical use by  $\frac{1}{4} \frac{0}{3} \frac{0}{4}$  of the electromotive force between the poles or electrodes of the voltaic cell known as Clark's cell, at a temperature of  $15^{\circ}$  C., and prepared in the manner described in the accompanying specification.\*

“As a unit of quantity, the *international coulomb*, which is the quantity of electricity transferred by a current of one international ampère in one second.

“As a unit of capacity, the *international farad*, which is the capacity of a condenser charged to a potential of one international volt by one international coulomb of electricity.†

“As a unit of work, the *joule*, which is equal to  $10^7$  units of work in the c. g. s. system, and which is represented sufficiently well for practical use by the energy expended in one second by an international ampère in an international ohm.

“As a unit of power, the *watt*, which is equal to  $10^7$  units of power in the c. g. s. system, and which is represented sufficiently well for practical use by the work done at the rate of one joule per second.

“As the unit of induction, the *henry*, which is the induction in a circuit when the electromotive force induced in this circuit is one international volt, while the inducing current varies at the rate of one ampère per second.

“The Chamber also voted that it was not wise to adopt or recommend a standard of light at the present time.”

By an Act of Congress approved July 12th, 1894, the units recommended by the Chicago Congress were adopted in this country with only some unimportant verbal changes in the definitions.

By an Order in Council of date August 23d, 1894, the British Board of Trade adopted the ohm, the ampere, and the volt, substantially as recommended by the Chicago Congress. The other units were not legalized in Great Britain. They are, however, in general use in that country and all over the world.

“The kathode on which the silver is to be deposited should take the form of a platinum bowl not less than 10 centimeters in diameter and from 4 to 5 centimeters in depth.

“The anode should be a plate of pure silver some 30 square centimeters in area and 2 or 3 millimeters in thickness.

“This is supported horizontally in the liquid near the top of the solution by a platinum wire passed through holes in the plate at opposite corners. To prevent the disintegrated silver which is formed on the anode from falling on to the kathode, the anode should be wrapped round with pure filter paper, secured at the back with sealing wax.

“The liquid should consist of a neutral solution of pure silver nitrate, containing about 15 parts by weight of the nitrate to 85 parts of water.

“The resistance of the voltmeter changes somewhat as the current passes. To prevent these changes having too great an effect on the current, some resistance besides that of the voltmeter should be inserted in the circuit. The total metallic resistance of the circuit should not be less than 10 ohms.”

\* A committee, consisting of Messrs. Helmholtz, Ayrton, and Carhart, was appointed to prepare specifications for the Clark's cell, but no report was made, on account of Helmholtz's death.

† The one millionth part of the farad is more commonly used in practical measurements, and is called the microfarad.

# PHYSICAL TABLES

TABLE 1.  
FUNDAMENTAL AND DERIVED UNITS.

To change a quantity from one system of units to another: substitute in the corresponding conversion factor from the following table the ratio of the magnitudes of the *old* units to the *new* and multiply the old quantity by the resulting number. For example: to reduce velocity in miles per hour to feet per second, the conversion factor is  $l t^{-1}$ ;  $l = 5280/1$ ,  $t = 3600/1$ , therefore the factor =  $5280/3600 = 1.467$ .

## (a) FUNDAMENTAL UNITS.

| Name of Unit.                | Symbol. | Conversion Factor. |
|------------------------------|---------|--------------------|
| Length.                      | L       | $l$                |
| Mass.                        | M       | $m$                |
| Time.                        | T       | $t$                |
| Temperature.                 | Θ       | $\theta$           |
| Electric Inductive Capacity. | K       | $k$                |
| Magnetic Inductive Capacity. | P       | $p$                |

## (b) DERIVED UNITS.

## I. Geometric and Dynamic Units.

| Name of Unit.  | Conversion Factor. |
|--|--------------------|
| Area.  | $l^2$              |
| Volume.  | $l^3$              |
| Angle.   | I                  |
| Solid Angle.   | I                  |
| Curvature.   | $l^{-1}$           |
| Tortuosity.  | $l^{-1}$           |
| Specific curvature of a surface.                                     | $l^{-2}$           |
| Angular velocity.  | $t^{-1}$           |
| Angular acceleration.  | $t^{-2}$           |
| Linear velocity.   | $l t^{-1}$         |
| Linear acceleration.   | $l t^{-2}$         |
| Density.   | $m l^{-3}$         |
| Moment of inertia.   | $m l^2$            |
| Intensity of attraction, or "force at a point."                      | $l t^{-2}$         |
| Absolute force of a centre of attraction, or "strength of a centre." | $l^3 t^{-2}$       |
| Momentum.  | $m l t^{-1}$       |
| Moment of momentum, or angular momentum.                             | $m l^2 t^{-1}$     |
| Force.   | $m l t^{-2}$       |
| Moment of a couple, or torque.                                       | $m l^2 t^{-2}$     |
| Intensity of stress.   | $m l^{-1} t^{-2}$  |
| Modulus of elasticity.   | $m l^{-1} t^{-2}$  |
| Work and energy.   | $m l^2 t^{-2}$     |
| Resilience.  | $m l^{-1} t^{-2}$  |
| Power or activity.   | $m l^2 t^{-3}$     |

## FUNDAMENTAL AND DERIVED UNITS.

## II. Heat Units.

| Name of Unit.                             | Conversion Factor.       |
|---|--------------------------|
| Quantity of heat (thermal units).         | $m \theta$               |
| “ “ (thermometric units).                 | $l^3 \theta$             |
| “ “ (dynamical units).                    | $m l^2 t^{-2}$           |
| Coefficient of thermal expansion.         | $\theta^{-1}$            |
| Conductivity (thermal units).             | $m l^{-1} t^{-1}$        |
| “ (thermometric units), or diffusivity.   | $l^2 t^{-1}$             |
| “ (dynamical units).                      | $m l t^{-3} \theta^{-1}$ |
| Thermal capacity.                         | $m$                      |
| Latent heat (thermal units).              | $\theta$                 |
| “ “ (dynamical units).                    | $l^2 t^{-2}$             |
| Joule's equivalent.                       | $l^2 t^{-2} \theta$      |
| Entropy (heat measured in thermal units). | $m$                      |
| “ ( “ “ “ dynamical units).               | $m l^2 t^{-2} \theta$    |

## III. Magnetic and Electric Units.

| Name of Unit.  | Conversion factor for electrostatic system.                | Conversion factor for electromagnetic system.              |
|--|--|--|
| Magnetic pole, or quantity of magnetism. }                 | $m^{\frac{1}{2}} l^{\frac{1}{2}} k^{-\frac{1}{2}}$         | $m^{\frac{1}{2}} l^{\frac{1}{2}} t^{-1} p^{\frac{1}{2}}$   |
| Density of surface distribution of magnetism. }            | $m^{\frac{1}{2}} l^{-\frac{1}{2}} k^{-\frac{1}{2}}$        | $m^{\frac{1}{2}} l^{-\frac{1}{2}} t^{-1} p^{\frac{1}{2}}$  |
| Intensity of magnetic field. }                             | $m^{\frac{1}{2}} l^{\frac{1}{2}} t^{-2} k^{\frac{1}{2}}$   | $m^{\frac{1}{2}} l^{-\frac{1}{2}} t^{-1} p^{-\frac{1}{2}}$ |
| Magnetic potential. }                                      | $m^{\frac{1}{2}} l^{\frac{1}{2}} t^{-2} k^{\frac{1}{2}}$   | $m^{\frac{1}{2}} l^{\frac{1}{2}} t^{-1} p^{-\frac{1}{2}}$  |
| Magnetic moment. }   | $m^{\frac{1}{2}} l^{\frac{1}{2}} k^{-\frac{1}{2}}$         | $m^{\frac{1}{2}} l^{\frac{1}{2}} t^{-1} p^{\frac{1}{2}}$   |
| Intensity of magnetisation. }                              | $m^{\frac{1}{2}} l^{-\frac{1}{2}} k^{-\frac{1}{2}}$        | $m^{\frac{1}{2}} l^{-\frac{1}{2}} t^{-1} p^{\frac{1}{2}}$  |
| Magnetic permeability. }                                   | I  | I  |
| Magnetic susceptibility and magnetic inductive capacity. } | $l^{-2} t^2 k^{-1}$  | $p$  |
| Quantity of electricity. }                                 | $m^{\frac{1}{2}} l^{\frac{1}{2}} t^{-1} k^{\frac{1}{2}}$   | $m^{\frac{1}{2}} l^{\frac{1}{2}} p^{-\frac{1}{2}}$         |
| Electric surface density and electric displacement. }      | $m^{\frac{1}{2}} l^{-\frac{1}{2}} t^{-1} k^{\frac{1}{2}}$  | $m^{\frac{1}{2}} l^{-\frac{1}{2}} p^{-\frac{1}{2}}$        |
| Intensity of electric field. }                             | $m^{\frac{1}{2}} l^{-\frac{1}{2}} t^{-1} k^{-\frac{1}{2}}$ | $m^{\frac{1}{2}} l^{\frac{1}{2}} t^{-2} p^{\frac{1}{2}}$   |
| Electric potential and e. m. f. }                          | $m^{\frac{1}{2}} l^{\frac{1}{2}} t^{-1} k^{-\frac{1}{2}}$  | $m^{\frac{1}{2}} l^{\frac{1}{2}} t^{-2} p^{\frac{1}{2}}$   |
| Capacity of a condenser. }                                 | $l k$  | $l^{-1} t^2 p^{-1}$  |
| Inductive capacity. }                                      | $k$  | $t^{-2} t^2 p^{-1}$  |
| Specific inductive capacity. }                             | I  | I  |
| Electric current. }  | $m^{\frac{1}{2}} l^{\frac{1}{2}} t^{-2} k^{\frac{1}{2}}$   | $m^{\frac{1}{2}} l^{\frac{1}{2}} t^{-1} p^{-\frac{1}{2}}$  |

According to an executive order dated April 15, 1893, the United States yard is defined as  $3600/3937$  meter, and the avoirdupois pound as  $1/2.20462$  kilogram.

1 meter (international prototype) =  $1553164.13$  times the wave-length of the red Cd. line. Benoit, Fabry and Perot. C. R. 144, 1907 differs only in the decimal portion from the measure of Michelson and Benoit 14 years earlier.

The length of the nautical mile given above and adopted by the U. S. Coast and Geodetic Survey many years ago, is defined as that of a minute of arc of a great circle of a sphere whose surface equals that of the earth (Clarke's spheroid of 1866).

By the concurrent action of the principal governments of the world an International Bureau of Weights and Measures has been established near Paris. Under the direction of the International Committee, two ingots were cast of pure platinum-iridium in the proportion of 9 parts of the former to 1 of the latter metal. From one of these a certain number of kilograms were prepared, from the other a definite number of meter bars. These standards of weight and length were intercompared, without preference, and certain ones were selected as International prototype standards. The others were distributed by lot, in September, 1889, to the different governments, and are called National prototype standards. Those apportioned to the United States were received in 1890, and are kept at the Bureau of Standards in Washington, D. C.

The metric system was legalized in the United States in 1866.

The International Standard Meter is derived from the Mètre des Archives, and its length is defined by the distance between two lines at 0° Centigrade, on a platinum-iridium bar deposited at the International Bureau of Weights and Measures.

The International Standard Kilogram is a mass of platinum-iridium deposited at the same place, and its weight in vacuo is the same as that of the Kilogram des Archives.

The liter is equal to the quantity of pure water at 4° C, 760 mm. Hg. pressure which weighs 1 kilogram = 1.00002 cu. dm. (Trav. et Mem. Bureau Intern. des P. et M. 14, 1910, Benoit.)

## EQUIVALENTS OF METRIC AND BRITISH IMPERIAL WEIGHTS AND MEASURES.\*

## (1) METRIC TO IMPERIAL.

## LINEAR MEASURE.

|                                 |   |   |                 |
|---------------------------------|---|---|-----------------|
| 1 millimeter (mm.)<br>(.001 m.) | } | = | 0.03937 in.     |
| 1 centimeter (.01 m.)           |   |   | 0.39370 "       |
| 1 decimeter (.1 m.)             | } | = | 3.93701 "       |
| 1 METER (m.) . . .              |   |   | 39.370113 "     |
|                                 | } | = | 3.280843 ft.    |
|                                 |   |   | 1.09361425 yds. |
| 1 dekameter<br>(10 m.)          | } | = | 10.93614 "      |
| 1 hectometer<br>(100 m.)        |   |   | 109.361425 "    |
| 1 kilometer<br>(1,000 m.)       | } | = | 0.62137 mile.   |
| 1 myriameter<br>(10,000 m.)     |   |   | 6.21372 miles.  |
| 1 micron . . . . .              | } | = | 0.001 mm.       |

## SQUARE MEASURE.

|   |   |   |                 |
|---|---|---|-----------------|
| 1 sq. centimeter . . .                    | } | = | 0.1550 sq. in.  |
| 1 sq. decimeter<br>(100 sq. centm.)       |   |   | 15.500 sq. in.  |
| 1 sq. meter or centiare<br>(100 sq. dcm.) | } | = | 10.7639 sq. ft. |
| 1 ARE (100 sq. m.)                        |   |   | 1.1960 sq. yds. |
| 1 hectare (100 ares<br>or 10,000 sq. m.)  | } | = | 2.4711 acres.   |

## CUBIC MEASURE.

|  |   |   |                    |
|--|---|---|--------------------|
| 1 cub. centimeter<br>(c.c.) (1,000 cubic<br>millimeters) | } | = | 0.0610 cub. in.    |
| 1 cub. decimeter<br>(c.d.) (1,000 cubic<br>centimeters)  |   |   | 61.024 " "         |
| 1 CUB. METER<br>(or stere<br>(1,000 c.d.))               | } | = | 35.3148 cub. ft.   |
|  |   |   | 1.307954 cub. yds. |

## MEASURE OF CAPACITY.

|  |   |   |                 |
|--|---|---|-----------------|
| 1 milliliter (ml.) (.001<br>liter)                         | } | = | 0.0610 cub. in. |
| 1 centiliter (.01 liter)                                   |   |   | 0.61024 " "     |
| 1 deciliter (.1 liter)                                     | } | = | 0.070 gill.     |
| 1 LITER (1,000 cub.<br>centimeters or 1<br>cub. decimeter) |   |   | 0.176 pint.     |
| 1 dekaliter (10 liters)                                    | } | = | 1.75980 pints.  |
| 1 hectoliter (100 " )                                      |   |   | 2.200 gallons.  |
| 1 kiloliter (1,000 " )                                     | } | = | 2.75 bushels.   |
|  |   |   | 3.437 quarters. |

## APOTHECARIES' MEASURE.

|                                    |   |   |                         |
|------------------------------------|---|---|-------------------------|
| 1 cubic centimeter (1<br>gram w't) | } | = | 0.03520 fluid ounce.    |
|                                    |   |   | 0.28157 fluid drachm.   |
| 1 cub. millimeter                  | } | = | 15.43236 grains weight. |
|                                    |   |   | 0.01693 minim.          |

## AVOIRDUPOIS WEIGHT.

|                                      |   |   |                     |

|                                      |   |   | 15.432.3564 grains. |
| 1 myriagram (10 kilog.)              | } | = | 22.04622 lbs.       |
| 1 quintal (100 " )                   |   |   | 1.96841 cwt.        |
| 1 millier or tonne<br>(1,000 kilog.) | } | = | 0.9842 ton.         |

## TROY WEIGHT.

|                  |   |   |                      |
|------------------|---|---|----------------------|
| 1 GRAM . . . . . | } | = | 0.03215 oz. Troy.    |
|                  |   |   | 0.64301 pennyweight. |
|                  | } | = | 15.43236 grains.     |

## APOTHECARIES' WEIGHT.

|                  |   |   |                  |
|------------------|---|---|------------------|
| 1 GRAM . . . . . | } | = | 0.25721 drachm.  |
|                  |   |   | 0.77162 scruple. |
|                  | } | = | 15.43236 grains. |

NOTE.—The METER is the length, at the temperature of 0° C., of the platinum-iridium bar deposited at the International Bureau of Weights and Measures at Sèvres, near Paris, France.

The present legal equivalent of the meter is 39.370113 inches, as above stated.

The KILOGRAM is the mass of a platinum-iridium weight deposited at the same place.

The LITER contains one kilogram weight of distilled water at its maximum density (4° C.), the barometer being at 760 millimeters.

\*In accordance with the schedule adopted under the Weights and Measures (metric system) Act, 1897.

## EQUIVALENTS OF BRITISH IMPERIAL AND METRIC WEIGHTS AND MEASURES.

## (3) IMPERIAL TO METRIC.

## LINEAR MEASURE.

|                                    |         |                 |
|------------------------------------|---------|-----------------|
| 1 inch . . . . .                   | =       | { 25.400 milli- |
|                                    |         | meters.         |
| 1 foot (12 in.) . . . . .          | =       | 0.30480 meter.  |
| 1 YARD (3 ft.) . . . . .           | =       | 0.914399 "      |
| 1 pole (5½ yd.) . . . . .          | =       | 5.0292 meters.  |
| 1 chain (22 yd. or<br>100 links) } | =       | 20.1168 "       |
| 1 furlong (220 yd.) =              | 201.168 | "               |
| 1 mile (1,760 yd.) . . . . .       | =       | { 1.6093 kilo-  |
|                                    |         | meters.         |

## SQUARE MEASURE.

|                           |                    |                   |
|---------------------------|--------------------|-------------------|
| 1 square inch . . . . .   | =                  | { 6.4516 sq. cen- |
|                           |                    | timeters.         |
| 1 sq. ft. (144 sq. in.) = | { 9.2903 sq. deci- |                   |
|                           | meters.            |                   |
| 1 SQ. YARD (9 sq. ft.) =  | { 0.836126 sq.     |                   |
|                           | meters.            |                   |
| 1 perch (30¼ sq. yd.) =   | { 25.293 sq. me-   |                   |
|                           | ters.              |                   |
| 1 rood (40 perches) =     | 10.117 ares.       |                   |
| 1 ACRE (4840 sq. yd.) =   | 0.40468 hectare.   |                   |
| 1 sq. mile (640 acres) =  | { 259.00 hectares. |                   |

## CUBIC MEASURE.

|                                  |                          |
|----------------------------------|--------------------------|
| 1 cub. inch =                    | 16.387 cub. centimeters. |
| 1 cub. foot (1728<br>cub. in.) } | = { 0.028317 cub. me-    |
|                                  | ter, or 28.317           |
|                                  | cub. decimeters.         |
| 1 CUB. YARD (27<br>cub. ft.) }   | = { 0.76455 cub. meter.  |

## APOTHECARIES' MEASURE.

|   |   |                   |
|---|---|-------------------|
| 1 gallon (8 pints or<br>160 fluid ounces) } | = | 4.5459631 liters. |
| 1 fluid ounce, f ʒ }                        | = | { 28.4123 cubic   |
| (8 drachms)                                 |   | centimeters.      |
| 1 fluid drachm, f ʒ }                       | = | { 3.5515 cubic    |
| (60 minims)                                 |   | centimeters.      |
| 1 minim, ℥ (0.091146<br>grain weight) }     | = | { 0.05919 cubic   |
|   |   | centimeters.      |

NOTE. — The Apothecaries' gallon is of the same capacity as the Imperial gallon.

## MEASURE OF CAPACITY.

|                               |                    |                   |
|-------------------------------|--------------------|-------------------|
| 1 gill . . . . .              | =                  | 1.42 deciliters.  |
| 1 pint (4 gills) . . . . .    | =                  | 0.568 liter.      |
| 1 quart (2 pints) . . . . .   | =                  | 1.136 liters.     |
| 1 GALLON (4 quarts) =         | 4.5459631 "        |                   |
| 1 peck (2 galls.) . . . . .   | =                  | 9.092 "           |
| 1 bushel (8 galls.) . . . . . | =                  | 3.637 dekaliters. |
| 1 quarter (8 bushels) =       | 2.909 hectoliters. |                   |

## AVOIRDUPOIS WEIGHT.

|                                       |   |                    |
|---------------------------------------|---|--------------------|
| 1 grain . . . . .                     | = | { 64.8 milli-      |
|                                       |   | grams.             |
| 1 dram . . . . .                      | = | 1.772 grams.       |
| 1 ounce (16 dr.) . . . . .            | = | 28.350 "           |
| 1 POUND (16 oz. or<br>7,000 grains) } | = | 0.45359243 kilogr. |
| 1 stone (14 lb.) . . . . .            | = | 6.350 "            |
| 1 quarter (28 lb.) . . . . .          | = | 12.70 "            |
| 1 hundredweight<br>(112 lb.) }        | = | { 50.80 "          |
|                                       |   | 0.5080 quintal.    |
| 1 ton (20 cwt.) . . . . .             | = | { 1.0160 tonnes    |
|                                       |   | or 1016 kilo-      |
|                                       |   | grams.             |

## TROY WEIGHT.

|  |   |                |
|--|---|----------------|
| 1 TROY OUNCE (480<br>grains avoird.) } | = | 31.1035 grams. |
| 1 pennyweight (24<br>grains) }         | = | 1.5552 "       |

NOTE. — The Troy grain is of the same weight as the Avoirdupois grain.

## APOTHECARIES' WEIGHT.

|                                |                |
|--------------------------------|----------------|
| 1 ounce (8 drachms) =          | 31.1035 grams. |
| 1 drachm, ʒi (3 scrup-         | = 3.888 "      |
| ples)                          |                |
| 1 scruple, ʒi (20<br>grains) } | = 1.296 "      |

NOTE. — The Apothecaries' ounce is of the same weight as the Troy ounce. The Apothecaries' grain is also of the same weight as the Avoirdupois grain.

NOTE. — The YARD is the length at 62° Fahr., marked on a bronze bar deposited with the Board of Trade.

The POUND is the weight of a piece of platinum weighed in vacuo at the temperature of 0° C., and which is also deposited with the Board of Trade.

The GALLON contains 10 lb. weight of distilled water at the temperature of 62° Fahr., the barometer being at 30 inches.

## EQUIVALENTS OF BRITISH IMPERIAL AND METRIC WEIGHTS AND MEASURES.

## (4) IMPERIAL TO METRIC.

VOLUME OF A CLASS VESSEL FROM THE WEIGHT OF ITS EQUIVALENT VOLUME OF MERCURY OR WATER.

If a glass vessel contains at  $t^{\circ}C$ ,  $P$  grammes of mercury, weighted with brass weights in air at 760 mm. pressure, then its volume in c. cm.

$$\text{at the same temperature, } t, : V = PR = \frac{P\rho}{d},$$

$$\text{at another temperature, } t_1, : V = PR_1 = \frac{P\rho}{d} \{1 + \gamma(t_1 - t)\}$$

$\rho$  = the weight, reduced to vacuum, of the mass of mercury or water which, weighed with brass weights, equals 1 gram;

$d$  = the density of mercury or water at  $t^{\circ}C$ ,

and  $\gamma = 0.000025$ , is the cubical expansion coefficient of glass.

TABLE 23. — Least Squares.

$$\text{Values of } P = \frac{2}{\sqrt{\pi}} \int_0^{hx} e^{-(hx)^2} d(hx).$$

This table gives the value of P, the probability of an observational error having a value positive or negative equal to or less than  $x$  when  $h$  is the measure of precision,  $P = \frac{2}{\sqrt{\pi}} \int_0^{hx} e^{-(hx)^2} d(hx)$ . For values of the inverse function see the table on Diffusion.

Taken from a paper by Dr. James Burgess 'on the Definite Integral  $\frac{2}{\sqrt{\pi}} \int_0^t e^{-t^2} dt$ , with Extended Tables of Values.' Trans. Roy. Soc. of Edinburgh, vol. xxxix, 1900, p. 257.

LEAST SQUARES.

This table gives the values of the probability P, as defined in last table, corresponding to different values of  $x/r$  where  $r$  is the "probable error." The probable error  $r$  is equal to  $0.47694/k$ .

| $\frac{x}{r}$ | 0      | 1      | 2      | 3      | 4      | 5      | 6      | 7      | 8      | 9      |

| 70    | .0015 | .0014 | .0014 | .0014  | .0013  | .0013  | .0013  | .0013  | .0012  |
| 80    | .0012 | .0012 | .0011 | .0011  | .0011  | .0011  | .0011  | .0010  | .0010  |
| 90    | .0010 | .0010 | .0010 | .0009  | .0009  | .0009  | .0009  | .0009  | .0009  |

Observation equations :

$$\begin{aligned} a_1z_1 + b_1z_2 + \dots + l_1z_q &= M_1, \text{ weight } p_1 \\ a_2z_1 + b_2z_2 + \dots + l_2z_q &= M_2, \text{ weight } p_2 \\ \dots &\dots \\ a_nz_1 + b_nz_2 + \dots + l_nz_q &= M_n, \text{ weight } p_n. \end{aligned}$$

Auxiliary equations :

$$\begin{aligned} [paa] &= p_1a_1^2 + p_2a_2^2 + \dots + p_na_n^2. \\ [pab] &= p_1a_1b_1 + p_2a_2b_2 + \dots + p_na_nb_n. \\ [paM] &= p_1a_1M_1 + p_2a_2M_2 + \dots + p_na_nM_n. \end{aligned}$$

Normal equations :

$$\begin{aligned} [paa]z_1 + [pab]z_2 + \dots + [pal]z_q &= [paM] \\ [pab]z_1 + [pbb]z_2 + \dots + [pbl]z_q &= [pbM] \\ \dots &\dots \\ [pla]z_1 + [plb]z_2 + \dots + [pll]z_q &= [plM]. \end{aligned}$$

Solution of normal equations in the form,

$$\begin{aligned} z_1 &= A_1[paM] + B_1[pbM] + \dots + L_1[plM] \\ z_2 &= A_2[paM] + B_2[pbM] + \dots + L_2[plM] \\ \dots &\dots \\ z_q &= A_n[paM] + B_n[pbM] + \dots + L_n[plM], \end{aligned}$$

gives :

$$\begin{aligned} \text{weight of } z_1 = p_{z_1} &= (A_1)^{-1}; \text{ probable error of } z_1 = \frac{r}{\sqrt{p_{z_1}}} \\ \text{weight of } z_2 = p_{z_2} &= (B_2)^{-1}; \text{ probable error of } z_2 = \frac{r}{\sqrt{p_{z_2}}} \\ \dots &\dots \\ \text{weight of } z_q = p_{z_q} &= (L_n)^{-1}; \text{ probable error of } z_q = \frac{r}{\sqrt{p_{z_q}}} \end{aligned}$$

wherein

$$\begin{aligned} r &= \text{probable error of observation of weight unity} \\ &= 0.6745 \sqrt{\frac{\sum pv^2}{n-q}}. \quad (q \text{ unknowns.}) \end{aligned}$$

Arithmetical mean, n observations:

$$\begin{aligned} r &= 0.6745 \sqrt{\frac{\sum v^2}{n-1}} = \frac{0.8453 \sum v}{\sqrt{n(n-1)}} \quad (\text{approx.}) = \text{probable error of observation of weight unity.} \\ r_0 &= 0.6745 \sqrt{\frac{\sum v^2}{n(n-1)}} = \frac{0.8453 \sum v}{n\sqrt{n-1}} \quad (\text{approx.}) = \text{probable error of mean.} \end{aligned}$$

Weighted mean, n observations:

$$r = 0.6745 \sqrt{\frac{\sum p v^2}{n-1}}; \quad r_0 = \frac{r}{\sqrt{\sum p}} = 0.6745 \sqrt{\frac{\sum p v^2}{(n-1) \sum p}}$$

Probable error (R) of a function (Z) of several observed quantities  $z_1, z_2, \dots$  whose probable errors are respectively,  $r_1, r_2, \dots$

$$\begin{aligned} Z &= f(z_1, z_2, \dots) \\ R^2 &= \left(\frac{\partial Z}{\partial z_1}\right)^2 r_1^2 + \left(\frac{\partial Z}{\partial z_2}\right)^2 r_2^2 + \dots \end{aligned}$$

Examples :

$$\begin{aligned} Z &= z_1 \pm z_2 + \dots & R^2 &= r_1^2 + r_2^2 + \dots \\ Z &= Az_1 \pm Az_2 \pm \dots & R^2 &= A^2 r_1^2 + B^2 r_2^2 + \dots \\ Z &= z_1 z_2. & R^2 &= z_1 r_2^2 + z_2 r_1^2. \end{aligned}$$

TABLE 30.  
DIFFUSION.

## GAMMA FUNCTION.\*

$$\text{Value of } \log \int_0^{\infty} e^{-x} x^{n-1} dx + 10.$$

Values of the logarithms + 10 of the "Second Eulerian Integral" (Gamma function)  $\int_0^{\infty} e^{-x} x^{n-1} dx$  or  $\log \Gamma(n) + 10$  for values of  $n$  between 1 and 2. When  $n$  has values not lying between 1 and 2 the value of the function can be readily calculated from the equation  $\Gamma(n+1) = n\Gamma(n) = n(n-1) \dots (n-r)\Gamma(n-r)$ .

| $n$         | 0         | 1      | 2     | 3     | 4     | 5     | 6     | 7     | 8     | 9     |

ELLIPTIC INTEGRALS.

$$\text{Values of } \int_0^{\frac{\pi}{2}} (1 - \sin^2 \theta \sin^2 \phi)^{\pm \frac{1}{2}} d\phi.$$

This table gives the values of the integrals between 0 and  $\pi/2$  of the function  $(1 - \sin^2 \theta \sin^2 \phi)^{\pm \frac{1}{2}} d\phi$  for different values of the modulus corresponding to each degree of  $\theta$  between 0 and  $90^\circ$ .

| $\theta$   | $\int_0^{\frac{\pi}{2}} \frac{d\phi}{(1 - \sin^2 \theta \sin^2 \phi)^{\frac{1}{2}}}$ |          | $\int_0^{\frac{\pi}{2}} (1 - \sin^2 \theta \sin^2 \phi)^{\frac{1}{2}} d\phi$ |          | $\theta$   | $\int_0^{\frac{\pi}{2}} \frac{d\phi}{(1 - \sin^2 \theta \sin^2 \phi)^{\frac{3}{2}}}$ |          | $\int_0^{\frac{\pi}{2}} (1 - \sin^2 \theta \sin^2 \phi)^{\frac{3}{2}} d\phi$ |          |

## MOMENTS OF INERTIA, RADII OF GYRATION, AND WEIGHTS.

In each case the axis is supposed to traverse the centre of gravity of the body. The axis is one of symmetry. The mass of a unit of volume is  $w$ .

| Body.   | Axis.                  | Weight.                       | Moment of Inertia I.  | Square of Radius of Gyration $\rho_g^2$ . |
|---|------------------------|-------------------------------|---|---|
| Sphere of radius $r$  | Diameter               | $\frac{4\pi w r^3}{3}$        | $\frac{8\pi w r^5}{15}$   | $\frac{2r^2}{5}$                          |
| Spheroid of revolution, polar axis $2a$ , equatorial diameter $2r$          | Polar axis             | $\frac{4\pi w a r^2}{3}$      | $\frac{8\pi w a r^4}{15}$   | $\frac{2r^2}{5}$                          |
| Ellipsoid, axes $2a, 2b, 2c$  | Axis $2a$              | $\frac{4\pi w abc}{3}$        | $\frac{4\pi w abc(b^2+c^2)}{15}$                                  | $\frac{b^2+c^2}{5}$                       |
| Spherical shell, external radius $r$ , internal $r'$                        | Diameter               | $\frac{4\pi w (r^3-r'^3)}{3}$ | $\frac{8\pi w (r^5-r'^5)}{15}$                                    | $\frac{2(r^5-r'^5)}{5(r^3-r'^3)}$         |
| Ditto, insensibly thin, radius $r$ , thickness $dr$                         | Diameter               | $4\pi w r^2 dr$               | $\frac{8\pi w r^4 dr}{3}$   | $\frac{2r^2}{3}$                          |
| Circular cylinder, length $2a$ , radius $r$                                 | Longitudinal axis $2a$ | $2\pi w a r^2$                | $\pi w a r^4$   | $\frac{r^2}{2}$                           |
| Elliptic cylinder, length $2a$ , transverse axes $2b, 2c$                   | Longitudinal axis $2a$ | $2\pi w abc$                  | $\frac{\pi w abc(b^2+c^2)}{2}$                                    | $\frac{b^2+c^2}{4}$                       |
| Hollow circular cylinder, length $2a$ , external radius $r$ , internal $r'$ | Longitudinal axis $2a$ | $2\pi w a (r^2-r'^2)$         | $\pi w a (r^4-r'^4)$  | $\frac{r^2+r'^2}{2}$                      |
| Ditto, insensibly thin, thickness $dr$                                      | Longitudinal axis $2a$ | $4\pi w a r dr$               | $4\pi w a r^3 dr$   | $r^2$                                     |
| Circular cylinder, length $2a$ , radius $r$                                 | Transverse diameter    | $2\pi w a r^2$                | $\frac{\pi w a r^2(3r^2+4a^2)}{6}$                                | $\frac{r^2}{4} + \frac{a^2}{3}$           |
| Elliptic cylinder, length $2a$ , transverse axes $2a, 2b$                   | Transverse axis $2b$   | $2\pi w abc$                  | $\frac{\pi w abc(3c^2+4a^2)}{6}$                                  | $\frac{c^2}{4} + \frac{a^2}{3}$           |
| Hollow circular cylinder, length $2a$ , external radius $r$ , internal $r'$ | Transverse diameter    | $2\pi w a (r^2-r'^2)$         | $\frac{\pi w a}{6} \left\{ 3(r^4-r'^4) + 4a^2(r^2-r'^2) \right\}$ | $\frac{r^2+r'^2}{4} + \frac{a^2}{3}$      |
| Ditto, insensibly thin, thickness $dr$                                      | Transverse diameter    | $4\pi w a r dr$               | $\pi w a (2r^3 + \frac{4}{3}a^2 r) dr$                            | $\frac{r^2}{2} + \frac{a^2}{3}$           |
| Rectangular prism, dimensions $2a, 2b, 2c$                                  | Axis $2a$              | $8wabc$                       | $\frac{8wabc(b^2+c^2)}{3}$  | $\frac{b^2+c^2}{3}$                       |
| Rhombic prism, length $2a$ , diagonals $2b, 2c$                             | Axis $2a$              | $4wabc$                       | $\frac{2wabc(b^2+c^2)}{3}$  | $\frac{b^2+c^2}{6}$                       |
| Ditto   | Diagonal $2b$          | $4wabc$                       | $\frac{2wabc(c^2+2a^2)}{3}$                                       | $\frac{c^2}{6} + \frac{a^2}{3}$           |

(Taken from Rankine.)

## STRENGTH OF MATERIALS.

The strength of most materials varies so that the following figures serve only as a rough indication of the strength of a particular sample.

TABLE 35 (a). — Metals.

| Name of Metal.  | Tensile strength in pounds per sq. in. |
|---|--|
| Aluminum wire   | 30000-40000                            |
| Brass wire  | 50000-150000                           |
| Bronze wire, phosphor, hard-drawn   | 110000-140000                          |
| Bronze wire, silicon, hard-drawn  | 95000-115000                           |
| Bronze: Cu, 58.54 parts; Zn, 38.70; Al, 0.21; with 2.55 parts of the alloy, Sn, 29.03, wrought iron, 58.06, ferromanganese, 12.91 | 60000-75000                            |
| Copper wire, hard-drawn   | 60000-70000                            |
| Gold wire   | 20000                                  |
| Iron, cast  | 13000-33000                            |
| “ wire, hard-drawn  | 80000-120000                           |
| “ “ annealed  | 50000-60000                            |
| Lead, cast or drawn   | 2600-3300                              |
| Palladium *   | 39000                                  |
| Platinum * wire   | 50000                                  |
| Silver * wire   | 42000                                  |
| Steel   | 80000-330000                           |
| “ wire, maximum   | 460000                                 |
| “ Specially treated nickel-steel, approx. comp. 0.40 C; 3.25 Ni; treatment secret   | 250000                                 |
| “ piano wire, 0.033 in. diam.   | 357000-390000                          |
| “ piano wire, 0.051 in. diam.   | 325000-337000                          |
| Tin, cast or drawn  | 4000-5000                              |
| Zinc, cast  | 7000-13000                             |
| “ drawn   | 22000-30000                            |

According to Boys, quartz fibres have a tensile strength of between 116000 and 167000 pounds per square inch.

\* Authority of Wertheim.

TABLE 35 (b). — Stones.\*

| Material.  | Size of test piece. | Resistance to crushing in pds. per sq. in. |
|------------|---------------------|--|
| Marble     | 4 in. cubes         | 7600-20700                                 |
| Tufa       | 2 “ “               | 7700-11600                                 |
| Brownstone | - - -               | 7300-23600                                 |
| Sandstone  | 4 in. cubes         | 2400-29300                                 |
| Granite    | 4 “ “               | 9700-34000                                 |
| Limestone  | 4 “ “               | 6000-25000                                 |

TABLE 35 (c). — Brick.\*

| Kind of Brick. | Resistance to crushing in pds. per sq. in. |                 |
|----------------|--|-----------------|
|                | Tested flatwise.                           | Tested on edge. |
| Soft burned    | 1800-4000                                  | 1600-3000       |
| Medium burned  | 4000-6000                                  | 3000-4500       |
| Hard burned    | 6000-8500                                  | 4500-6500       |
| Vitrified      | 8500-25000                                 | 6500-20000      |
| Sand-lime      | 1800-4000                                  |                 |

Brick piers laid up in 1 part Portland cement, 3 of sand, have from 20 to 40 per cent the crushing strength of the brick.

\* Data furnished by the U. S. Geological Survey.

TABLE 35 (d). — Concretes.\*

| Coarse Aggregate. | Proportions by volume. Cement : sand : aggregate. | Size of test piece. | Resistance to crushing in pds. per sq. in. |
|-------------------|---|---------------------|--|
| Sandstone         | 1 : 5 : 14 to 1 : 1 : 5                           | 12 in. cube         | 1550-3860                                  |

## STRENGTH OF MATERIALS.

## Average Results of Timber Tests.

The test pieces were SMALL and SELECTED. Endwise compression tests of some of the first lot, made when green and containing over 40 per cent moisture, showed a diminishing in strength of 50 to 75 per cent.

See also Table 37. A particular sample may vary greatly from these data, which can indicate only in a general way the relative values of a kind of timber. Note that the data below are from selected samples and therefore probably high.

The upper lot are from the U. S. Forestry circular No. 15; the lower from the tests made for the 10th U. S. Census.

| NAME OF SPECIES.  | TRANSVERSE TESTS.                |                                     | COMPRESSION.           |                          | SHEAR-ING.                    |
|-------------------|----------------------------------|-------------------------------------|------------------------|--------------------------|-------------------------------|
|                   | Modulus of rupture. lbs./sq. in. | Modulus of elasticity. lbs./sq. in. | to grain. lbs./sq. in. | ⊥ to grain. lbs./sq. in. | Along the grain. lbs./sq. in. |
| Long-leaf pine    | 12,600                           | 2,070,000                           | 8,000                  | 1260                     | 835                           |

These unit stresses are for a green condition of the timber and are to be used without increasing the live-load stresses for impact.

\* Partially air-dry.

† L = length in inches. D = least side in inches.

SMITHSONIAN TABLES.

ELASTIC MODULI.

TABLE 38. — Rigidity Modulus.

If to the four consecutive faces of a cube a tangential stress is applied, opposite in direction on adjacent sides, the modulus of rigidity is obtained by dividing the numerical value of the tangential stress per unit area (kg. per sq. mm.) by the number representing the change of angles on the non-stressed faces, measured in radians.

## ELASTICITY OF CRYSTALS.\*

The formulæ were deduced from experiments made on rectangular prismatic bars cut from the crystal. These bars were subjected to cross bending and twisting and the corresponding Elastic Moduli deduced. The symbols  $\alpha$   $\beta$   $\gamma$ ,  $\alpha_1$   $\beta_1$   $\gamma_1$  and  $\alpha_2$   $\beta_2$   $\gamma_2$  represent the direction cosines of the length, the greater and the less transverse dimensions of the prism with reference to the principal axis of the crystal. E is the modulus for extension or compression, and T is the modulus for torsional rigidity. The moduli are in grams per square centimeter.

Barite.

$$\frac{10^{10}}{E} = 16.13\alpha^4 + 18.51\beta^4 + 10.42\gamma^4 + 2(38.79\beta^2\gamma^2 + 15.21\gamma^2\alpha^2 + 8.88\alpha^2\beta^2)$$

$$\frac{10^{10}}{T} = 69.52\alpha^4 + 117.66\beta^4 + 116.46\gamma^4 + 2(20.16\beta^2\gamma^2 + 85.29\gamma^2\alpha^2 + 127.35\alpha^2\beta^2)$$

Beryl (Emerald).

$$\frac{10^{10}}{E} = 4.325 \sin^4\phi + 4.619 \cos^4\phi + 13.328 \sin^2\phi \cos^2\phi \quad \left\{ \begin{array}{l} \text{where } \phi \phi_1 \phi_2 \text{ are the angles which} \\ \text{the length, breadth, and thickness} \\ \text{of the specimen make with the} \\ \text{principal axis of the crystal.} \end{array} \right.$$

$$\frac{10^{10}}{T} = 15.00 - 3.675 \cos^4\phi_2 - 17.536 \cos^2\phi \cos^2\phi_1$$

Fluorspar.

$$\frac{10^{10}}{E} = 13.05 - 6.26(\alpha^4 + \beta^4 + \gamma^4)$$

$$\frac{10^{10}}{T} = 58.04 - 50.08(\beta^2\gamma^2 + \gamma^2\alpha^2 + \alpha^2\beta^2)$$

Pyrite.

$$\frac{10^{10}}{E} = 5.08 - 2.24(\alpha^4 + \beta^4 + \gamma^4)$$

$$\frac{10^{10}}{T} = 18.60 - 17.95(\beta^2\gamma^2 + \gamma^2\alpha^2 + \alpha^2\beta^2)$$

Rock salt.

$$\frac{10^{10}}{E} = 33.48 - 9.66(\alpha^4 + \beta^4 + \gamma^4)$$

$$\frac{10^{10}}{T} = 154.58 - 77.28(\beta^2\gamma^2 + \gamma^2\alpha^2 + \alpha^2\beta^2)$$

Sylvine.

$$\frac{10^{10}}{E} = 75.1 - 48.2(\alpha^4 + \beta^4 + \gamma^4)$$

$$\frac{10^{10}}{T} = 306.0 - 192.8(\beta^2\gamma^2 + \gamma^2\alpha^2 + \alpha^2\beta^2)$$

Topaz.

$$\frac{10^{10}}{E} = 4.341\alpha^4 + 3.460\beta^4 + 3.771\gamma^4 + 2(3.879\beta^2\gamma^2 + 2.856\gamma^2\alpha^2 + 2.39\alpha^2\beta^2)$$

$$\frac{10^{10}}{T} = 14.88\alpha^4 + 16.54\beta^4 + 16.45\gamma^4 + 30.89\beta^2\gamma^2 + 40.89\gamma^2\alpha^2 + 43.51\alpha^2\beta^2$$

Quartz.

$$\frac{10^{11}}{E} = 12.734(1 - \gamma^2)^2 + 16.693(1 - \gamma^2)\gamma^2 + 9.705\gamma^4 - 8.460\beta\gamma(3\alpha^2 - \beta^2)$$

$$\frac{10^{10}}{T} = 19.665 + 9.060\gamma_2^2 + 22.984\gamma_2^2\gamma_1^2 - 16.920[(\gamma\beta_T + \beta\gamma_1)(3\alpha_1 - \beta\beta_1) - \beta_2\gamma_2]$$

\* These formulæ are taken from Voigt's papers (Wied. Ann. vols. 31, 34, and 35).

## COMPRESSIBILITY OF GASES.

## COMPRESSIBILITY OF LIQUIDS.

If  $V_1$  is the volume under pressure  $p_1$  atmospheres at  $t^\circ C$ , and  $V_2$  is volume at pressure  $p_2$  and the same temperature, then the compressibility coefficient may be defined at that temperature as :

$$\beta_t = \frac{1}{V_1} \cdot \frac{V_1 - V_2}{p_2 - p_1}$$

In absolute units (referred to megadynes) the coefficient is  $\frac{1}{1.0137} \beta_t$ .

| Substance.        | $t$ . | Pressures. | $\beta \cdot 10^6$ | Refer-<br>ence. | Substance.                                | $t$ . | Pressures. | $\beta \cdot 10^6$ | Refer-<br>ence. |

## SPECIFIC GRAVITIES CORRESPONDING TO THE BAUMÉ SCALE.

The specific gravities are for 15.56°C (60°F) referred to water at the same temperature as unity. For specific gravities less than unity the values are calculated from the formula :

$$\text{Degrees Baumé} = \frac{140}{\text{Specific Gravity}} - 130.$$

For specific gravities greater than unity from:

$$\text{Degrees Baumé} = 145 - \frac{145}{\text{Specific Gravity}}.$$

| Specific Gravities less than 1.    |                |       |       |       |       |       |       |       |       |       |

## REDUCTIONS OF WEIGHINGS IN AIR TO VACUO.

TABLE 58.

When the weight  $M$  in grams of a body is determined in air, a correction is necessary for the buoyancy of the air equal to  $M \delta (1/d - 1/d_1)$  where  $\delta$  = the density (wt. of 1 cc in grams = 0.0012) of the air during the weighing,  $d$  the density of the body,  $d_1$  that of the weights.  $\delta$  for various barometric values and humidities may be determined from Tables 153 to 155. The following table is computed for  $\delta = 0.0012$ . The corrected weight =  $M + kM/1000$ .

| Density of body weighed $d_1$ | Correction factor, $k$ .     |                   |                            | Density of body weighed $d$ | Correction factor, $k$ .     |                   |                            |
|-------------------------------|------------------------------|-------------------|----------------------------|-----------------------------|------------------------------|-------------------|----------------------------|
|                               | Pt. Ir. weights $d_1 = 21.5$ | Brass weights 8.4 | Quartz or Al. weights 2.65 |                             | Pt. Ir. weights $d_1 = 21.5$ | Brass weights 8.4 | Quartz or Al. weights 2.65 |
| .5                            | + 2.34                       | + 2.26            | + 1.95                     | 1.6                         | + 0.69                       | + 0.61            | + 0.30                     |

TABLE 59. — Reductions of Densities in Air to Vacuo.

(This correction may be accomplished through the use of the above table for each separate weighing.)

If  $s$  is the density of the substance as calculated from the uncorrected weights,  $S$  its true density, and  $L$  the true density of the liquid used, then the vacuum correction to be applied to the uncorrected density,  $s$ , is  $0.0012 (1 - s/L)$ .

Let  $W_s$  = uncorrected weight of substance,  $W_l$  = uncorrected weight of the liquid displaced by the substance, then by definition,  $s = LW_s/W_l$ . Assuming  $D$  to be the density of the balance of weights,  $W_s \{1 + 0.0012 (1/S - 1/D)\}$  and  $W_l \{1 + 0.0012 (1/L - 1/D)\}$  are the true weights of the substance and liquid respectively (assuming that the weighings are made under normal atmospheric conditions, so that the weight of 1 cc. of air is 0.0012 gram).

$$\text{Then the true density } S = \frac{W_s \{1 + 0.0012 (1/S - 1/D)\}}{W_l \{1 + 0.0012 (1/L - 1/D)\}} L.$$

But from above  $W_s/W_l = s/L$ , and since  $L$  is always large compared with 0.0012,  $S - s = 0.0012 (1 - s/L)$ .

The values of  $0.0012 (1 - s/L)$  for densities up to 20 and for liquids of density 1 (water), 0.852 (xylene) and 13.55 (mercury) follow:

(See reference below for discussion of density determinations).

| Density of substance $s$ | Corrections.      |                        |                         | Density of substance $s$ | Corrections.      |                         |

\* To reduce to pounds per cu. ft. multiply by 62.4.

† Where the temperature is not given, ordinary atmospheric temperature is understood.

Compiled from Clarke's Constants of Nature, Landolt-Börnstein-Meyerhoffer's Tables, and other sources. Where no authority is stated, the values are mostly means from various sources.

## DENSITY OR MASS IN GRAMS PER CUBIC CENTIMETER OF THE ELEMENTS, LIQUID OR SOLID.

## DENSITY OF CASES.

The following table gives the density of the gases at 0° C, 76 cm. pressure, at sea-level and latitude 45° relative to air as unity and under the same conditions; also the weight of one liter in grams and one cubic foot in pounds.

| Gas.                            | Specific Gravity. | Grams per liter. | Pounds per cubic foot. | Reference.                              |
|---------------------------------|-------------------|------------------|------------------------|---|
| Air                             | 1.000             | 1.2928           | .08071                 | Rayleigh; Leduc.                        |

Compiled partly from Landolt-Börnstein-Meyerhoffer's Physikalisch-Chemische Tabellen.

## DENSITY OF AQUEOUS SOLUTIONS.\*

The following table gives the density of solutions of various salts in water. The numbers give the weight in grams per cubic centimeter. For brevity the substance is indicated by formula only.

| Substance.                                    | Weight of the dissolved substance in 100 parts by weight of the solution. |       |       |       |       |       |       |       |       |      | Temp. C.     | Authority. |
|---|---|-------|-------|-------|-------|-------|-------|-------|-------|------|--------------|------------|
|   | 5   | 10    | 15    | 20    | 25    | 30    | 40    | 50    | 60    |      |              |            |

<sup>1</sup> According to P. Chappuis, Bureau international des Poids et Mesures, Travaux et Mémoires, 13; 1907.

VOLUME IN CUBIC CENTIMETERS AT VARIOUS TEMPERATURES OF  
A CUBIC CENTIMETER OF WATER FREE FROM AIR AT THE  
TEMPERATURE OF MAXIMUM DENSITY.

## Hydrogen Thermometer Scale.

**DENSITIES OF MIXTURES OF ETHYL ALCOHOL AND WATER IN GRAMS PER MILLILITER.**

The densities in this table are numerically the same as specific gravities at the various temperatures in terms of water at 4° C. as unity. Based upon work done at U. S. Bureau of Standards. See Bulletin Bur. Stds. vol. 9, no. 3; contains extensive bibliography; also Circular 19, 1913.

## VELOCITY OF SOUND IN SOLIDS.

The numbers given in this table refer to the velocity of sound along a bar of the substance, and hence depend on the Young's Modulus of elasticity of the material. The elastic constants of most of the materials given in this table vary through a somewhat wide range, and hence the numbers can only be taken as rough approximations to the velocity which may be obtained in any particular case. When temperatures are not marked, between 10° and 20° is to be understood.

| Substance.                                   | Temp. C. | Velocity in meters per second. | Velocity in feet per second. | Authority.            |

## VELOCITY OF SOUND IN LIQUIDS AND GASES.

For gases, the velocity of sound =  $\sqrt{\gamma P/\rho}$ , where P is the pressure,  $\rho$  the density, and  $\gamma$  the ratio of specific heat at constant pressure to that at constant volume (see Table 265).

| Substance.                             | Temp. C. | Velocity in meters per second. | Velocity in feet per second. | Authority.         |

NOTE: The values from Ammonia to Methane inclusive are for closed tubes.

MUSICAL SCALES.

The pitch relations between two notes may be expressed precisely (1) by the ratio of their vibration frequencies; (2) by the number of equally-tempered semitones between them (E. S.); also, less conveniently, (3) by the common logarithm of the ratio in (1); (4) by the lengths of the two portions of the tense string which will furnish the notes; and (5) in terms of the octave as unity. The ratio in (4) is the reciprocal of that in (1); the number for (5) is 1/12 of that for (2); the number for (2) is nearly 40 times that for (3).

Table 79 gives data for the middle octave, including vibration frequencies for three standards of pitch;  $a = 435$  double vibrations per second, is the international standard and was adopted by the American Piano Manufacturers' Association. The "second-diatonic scale" of C-major is usually deduced, following Chladni, from the ratios of the three perfect major triads reduced to one octave, thus:

|    |   |    |   |    |   |    |   |    |   |    |   |    |  |    |  |    |  |    |
|----|---|----|---|----|---|----|---|----|---|----|---|----|--|----|--|----|--|----|
| 4  | : | 5  | : | 6  | : | 5  | : | 6  |   |    |   |    |  |    |  |    |  |    |
| F  | : | A  | : | C  | : | E  | : | G  | : | B  | : | D  |  |    |  |    |  |    |
| 16 |   | 20 |   | 24 |   | 27 |   | 30 |   | 32 |   | 36 |  | 40 |  | 45 |  | 48 |

Other equivalent ratios and their values in E. S. are given in Table 80. By transferring D to the left and using the ratio 10 : 12 : 15 the scale of A-minor is obtained, which agrees with that of C-major except that  $D = 26 \frac{2}{3}$ . Nearly the same ratios are obtained from a series of harmonics beginning with the eighth; also by taking 12 successive perfect or Pythagorean fifths or fourths and reducing to one octave. Such calculations are most easily made by adding and subtracting intervals expressed in E. S. The notes needed to furnish a just major scale in other keys may be found by successive transpositions by fifths or fourths as shown in Table 80. Disregarding the usually negligible difference of 0.02 E. S., the table gives the 24 notes to the octave required in the simplest enharmonic organ; the notes fall into pairs that differ by a comma, 0.22 E. S. The line "mean tone" is based on Dom Bedos' rule for tuning the organ (1746). The tables have been checked by the data in Ellis' Helmholtz's "Sensations of Tone."

**TABLE 82.**  
**GRAVITY.**

In this table the results of a number of the more recent gravity determinations are brought together. They serve to show the degree of accuracy which may be assumed for the numbers in Table 81. In general, gravity is a little lower than the calculated value for stations far inland and slightly higher on the coast line.

| Place.                                     | Latitude.<br>N. +, S. —. | Elevation<br>in meters. | Gravity, $\text{cm. sec}^2$ |                       | Reference. |

\* The data here given with regard to the different determinations which have been made of the length of the seconds pendulum are quoted from Harkness (Solar Parallax and its Related Constants, Washington, 1891).  
 † Calculated from a logarithmic expression given by Unferdinger.

## MISCELLANEOUS GEODETIC DATA.\*

TABLE 86.

Length of the seconds pendulum at sea level  $=l=39.012540+0.208268 \sin^2 \phi$  inches.  
 $=3.251045+0.017356 \sin^2 \phi$  feet.  
 $=0.9909910+0.005290 \sin^2 \phi$  meters.

Acceleration produced by gravity per second  
per second mean solar time  $=g=32.086528+0.171293 \sin^2 \phi$  feet.  
 $=977.9886+5.2210 \sin^2 \phi$  centimeters.

Equatorial radius  $=a=6378206$  meters;  
 $3963.225$  miles.

Polar semi-diameter  $=b=6356584$  meters;  
 $3949.790$  miles.

Reciprocal of flattening  $=\frac{a}{a-b}=295.0$

Square of eccentricity  $=e^2=\frac{a^2-b^2}{a^2}=0.006768658$

} Clarke Spheroid. } U. S. C. & G. Survey.

}  $6378388 \pm 18$  meters;  
 $3963.339$  miles.  
 $6356909$  meters;  
 $3949.992$  miles.  
 $297.0 \pm 0.5$   
 $0.0067237 \pm 0.0000120$ .

Difference between geographical and geocentric latitude  $=\phi - \phi' =$   
 $688.2242'' \sin 2 \phi - 1.1482'' \sin 4 \phi + 0.0026'' \sin 6 \phi$ .

Mean density of the Earth  $=5.5247 \pm 0.0013$  (Burgess Phys. Rev. 1902).

Continental surface density of the Earth  $=2.67$

Mean density outer ten miles of earth's crust  $=2.40$  } Harkness.

Moments of inertia of the Earth; the principal moments being taken as  $A, B,$  and  $C,$  and  $C$  the greater:

$$\frac{C-A}{C} = 0.00326521 = \frac{I}{300.259};$$

$$C-A = 0.001064767 E a^2;$$

$$A=B = 0.325029 E a^2;$$

$$C = 0.326094 E a^2;$$

where  $E$  is the mass of the Earth and  $a$  its equatorial semidiameter.

TABLE 87. — Length of Degrees on the Earth's Surface.

## MISCELLANEOUS ASTRONOMICAL DATA.

Length of sidereal year =  $365.2563578$  mean solar days;  
 =  $365$  days  $6$  hours  $9$  minutes  $9.314$  seconds.

Length of tropical year =  $365.242199870 - 0.0000062124 \frac{t-1850}{100}$  mean solar days;  
 =  $365$  days  $5$  hours  $48$  minutes  $\left(46.069 - 0.53675 \frac{t-1850}{100}\right)$  seconds.

Length of sidereal month  
 =  $27.321661162 - 0.00000026240 \frac{t-1800}{100}$  days;  
 =  $27$  days  $7$  hours  $43$  minutes  $\left(11.524 - 0.022671 \frac{t-1800}{100}\right)$  seconds.

Length of synodical month  
 =  $29.530588435 - 0.00000030696 \frac{t-1800}{100}$  days;  
 =  $29$  days  $12$  hours  $44$  minutes  $\left(2.841 - 0.026522 \frac{t-1800}{100}\right)$  seconds.

Length of sidereal day =  $86164.09965$  mean solar seconds.

N. B.—The factor containing  $t$  in the above equations (the year at which the values of the quantities are required) may in all ordinary cases be neglected.

Mean distance from earth to sun =  $92900000$  miles =  $149500000$  kilometers.

Eccentricity of the earth's orbit =  $e =$

$$0.01675104 - 0.0000004180(t-1900) - 0.000000126 \left(\frac{t-1900}{100}\right)^2.$$

Solar parallax =  $8.7997'' \pm 0.003$  (Weinberg, A. N. 165, 1904);

$8.807 \pm 0.0027$  (Hinks, Eros, 7);

$8.799$  (Samson, Jupiter satellites; Harvard observations).

Lunar parallax =  $3422.68''$ .

Mean distance from earth to moon =  $60.2669$  terrestrial radii;

=  $238854$  miles;

=  $384393$  kilometers.

Lunar inequality of the earth =  $Z = 6.45''$ .

Parallactic inequality of the moon =  $Q = 124.80''$ .

Mean motion of moon's node in  $365.25$  days =  $\mu = -19^\circ 21' 19.6191'' + 0.14136'' \left(\frac{t-1800}{100}\right)$

Eccentricity and inclination of the moon's orbit =  $e_2 = 0.05490807$ .

Delaunay's  $\gamma = \sin \frac{1}{2} I = 0.044886793$ .

$I = 5^\circ 08' 43.3546''$ .

Constant of nutation =  $9.2'$ .

Constant of aberration =  $20.4962 \pm 0.006$  (Weinberg, l. c.).\*

Time taken by light to traverse the mean radius of the earth's orbit

=  $498.82 \pm 0.1$  seconds (Weinberg);

=  $498.64$  (Samson).

Velocity of light =  $186330$  miles per second (Weinberg);

=  $299870 \pm 0.03$  kilometers per second.

General precession =  $50.2564'' + 0.000222(t-1900)$ .

Obliquity of the ecliptic =  $23^\circ 27' 8.26'' - 0.4684(t-1900)$ .

Gravitation constant =  $666.07 \times 10^{-10} \text{ cm}^3/\text{gr. sec}^2 \pm 0.16 \times 10^{-10}$ .

\* Recent work of Doolittle's and others indicates a value not less than  $20.51$ .

Table 89.—Planetary Data.

| Body.   | Reciprocals of masses. | Mean distance from the sun. Km. | Sidereal period. Mean days | Equatorial diameter. Km. | Inclination of orbit. | Mean density. H <sub>2</sub> O=1 | Gravity at surface. |
|---------|------------------------|---------------------------------|----------------------------|--------------------------|-----------------------|----------------------------------|---------------------|
| Sun     | 1.                     | —                               | —                          | 1391067                  | —                     | 1.39                             | 27.6                |
| Mercury | 6000000.               | 58 x 10 <sup>6</sup>            | 87.97                      | 4842                     | 7°.003                | 4.86                             | .3                  |

| Neptune | 19700.                 | 4495 "                          | 60188.71                   | 50040                    | 1.778                 | 1.28                             | .97                 |
| Moon    | † 81.45                | 38 x 10 <sup>4</sup>            | 27.32                      | 3473                     | 5.147                 | 3.37                             | .17                 |

\* Earth and moon. † Relative to earth. Inclination of axes: Sun 7°.25; Earth 23°.45; Mars 24°.6; Jupiter 3°.1; Saturn 26°.8; Neptune 27°.2. Others doubtful.

Table 90.—Equation of Time.

The equation of time when + is to be added to the apparent solar time to give mean time. When the place is not on a standard meridian (75'th, etc.) its difference in longitude in time from that meridian must be subtracted when east, added when west to get standard time (75'th meridian time, etc.). The equation varies from year to year cyclically, and the figure following the ± sign gives a rough idea of this variation.

|        | M.  | S.      |        | M. | S.      |         | M. | S.     |        | M.  | S.      |

Table 91.—Miscellaneous Astronomical Data.

Apex of Solar Motion:

From proper motions, R. A.<sub>1810</sub> = 17 51<sup>m</sup>, Dec.<sub>1810</sub> = + 31.4 (Weersma, Gron. Publ. 21.)

From radial velocities, R. A.<sub>1900</sub> = 17<sup>h</sup>54<sup>m</sup>, Dec.<sub>1900</sub> = + 25.1 (Campbell, Lick. Bull. 196.)

Velocity = 19.5 Km. per sec. (Campbell.)

Nearest star so far as known: α Centauri, parallax = 0.759'' (Gron. Publ. 24) distance = 4.3 light years.

Stars of both greatest proper motion and greatest radial velocity so far as known: \* Cordova, V243; proper motion = 8.70'' in position angle 130° radial velocity + 242 Km. per sec. (Campbell, Stellar Motions, 1913). Parallax = 0.319'' (Gron. Publ. 24, also proper motion). Distance = 10.2 light years.

Average velocities with regard to center of gravity of the stellar system, according to Campbell (Stellar Motion, 1913):

Type B Stars: 6.6 Km. per sec. Type G Stars: 15.0 Km. per sec.  
 " A " 10.9 " " " " K " 16.8 " " "  
 " F " 14.4 " " " " M " 17.1 " " "

Sun's magnitude = - 26.5, sending the earth 90,000,000,000 times as much light as the star Aldebaran.

Ratio of total radiation of sun to that of moon about 100,000 to 1 } Langley.  
 " " " light " " " " " " 400,000 to 1 }

\* Lalande, 1966, R.A.<sub>1910</sub> 1<sup>h</sup>3<sup>m</sup>.9, Dec.<sub>1910</sub> 61°.4' in 1913 was found to have a radial velocity (of approach) of 326 Km. per sec. (Mount Wilson Solar Observatory.)

## TERRESTRIAL MAGNETISM.

## Secular Change of Declination.

Changes in the magnetic declination between 1810, the date of the earliest available observations, and 1910, for one or more places in each state and territory.

| State. | Station.     | 1810  | 1820  | 1830  | 1840  | 1850  | 1860  | 1870  | 1880  | 1890  | 1900  | 1910  |

**TABLE 99.**  
**AGONIC LINE.**

The line of no declination appears to be still moving westward in the United States, but the line of no annual change is only a short distance to the west of it, so that it is probable that the extreme westerly position will soon be reached.

\* The height of the barometer is affected by the relative thermal expansion of the mercury and the glass, in the case of instruments graduated on the glass tube, and by the relative expansion of the mercury and the metallic inclosing case, usually of brass, in the case of instruments graduated on the brass case. This relative expansion is practically proportional to the first power of the temperature. The above tables of values of the coefficient of relative expansion will be found to give corrections almost identical with those given in the International Meteorological Tables. The numbers tabulated under  $\alpha$  are the values of  $\alpha$  in the equation  $H_t = H'_t - \alpha(t' - t)$  where  $H_t$  is the height at the standard temperature,  $H'_t$  the observed height at the temperature  $t'$ , and  $\alpha(t' - t)$  the correction for temperature. The standard temperature is  $0^\circ\text{C}$ . for the metric system and  $28^\circ.5\text{ F}$ . for the English system. The English barometer is correct for the temperature of melting ice at a temperature of approximately  $28^\circ.5\text{ F}$ ., because of the fact that the brass scale is graduated so as to be standard at  $62^\circ\text{ F}$ ., while mercury has the standard density at  $32^\circ\text{ F}$ .

EXAMPLE.—A barometer having a brass scale gave  $H = 765\text{ mm}$ . at  $25^\circ\text{ C}$ .; required, the corresponding reading at  $0^\circ\text{ C}$ . Here the value of  $\alpha$  is the mean of .1235 and .1251, or .1243;  $\therefore \alpha(t' - t) = .1243 \times 25 = 3.11$ . Hence  $H_0 = 765 - 3.11 = 761.89$ .

N. B.—Although  $\alpha$  is here given to three and sometimes to four significant figures, it is seldom worth while to use more than the nearest two-figure number. In fact, all barometers have not the same values for  $\alpha$ , and when great accuracy is wanted the proper coefficients have to be determined by experiment.

SMITHSONIAN TABLES.

**CORRECTION OF BAROMETER TO STANDARD GRAVITY.**

Altitude term. Correction is to be subtracted.

| Height above sea level in meters. | Observed height of barometer in millimeters. |      |      |       |       |       |       |       |      |       | Height above sea level in feet. |

## REDUCTION OF BAROMETER TO STANDARD GRAVITY.\*

Reduction to Latitude 45°.—English Scale.

N. B. From latitude 0° to 44° the correction is to be subtracted.  
 From latitude 90° to 46° the correction is to be added.

| Latitude. |     | Height of the barometer in inches. |                |                |                |                |                |                |                |                |                |                |                |

REDUCTION OF BAROMETER TO STANDARD GRAVITY.\*

Reduction to Latitude 45°. — Metric Scale.

N. B. — From latitude 0° to 44° the correction is to be subtracted.  
From latitude 90° to 46° the correction is to be added.

Scheel und Heuse, Annalen der Physik, 33, p. 291, 1910.

**AERODYNAMICS.**

The pressure on a plane surface normal to the wind is for ordinary wind velocities expressed by

$$P = k\tau wv^2$$

where  $k$  is a constant depending on the units employed,  $w$  the mass of unit volume of the air,  $a$  the area of the surface and  $v$  the velocity of the wind.\* Engineers generally use the table of values of  $P$  given by Smeaton in 1759. This table was calculated from the formula

$$P = .00492 v^2$$

and gives the pressure in pounds per square foot when  $v$  is expressed in miles per hour. The corresponding formula when  $v$  is expressed in feet per second is

$$P = .00228 v^2.$$

Later determinations do not agree well together, but give on the average somewhat lower values for the coefficient. The value of  $w$  depends, of course, on the temperature and the barometric pressure. Langley's experiments give  $k\tau w = .00166$  at ordinary barometric pressure and 10° C. temperature.

For planes inclined at an angle  $\alpha$  less than 90° to the direction of the wind the pressure may be expressed as

$$P_\alpha = F_\alpha P_{90}.$$

Table 108, founded on the experiments of Langley, gives the value of  $F_\alpha$  for different values of  $\alpha$ . The word *aspect*, in the headings, is used by him to define the position of the plane relative to the direction of motion. The numerical value of the aspect is the ratio of the linear dimension transverse to the direction of motion to the linear dimension, a vertical plane through which is parallel to the direction of motion.

**TABLE 108. — Values of  $F_\alpha$  in Equation  $P_\alpha = F_\alpha P_{90}$ .**

## AERODYNAMICS.

On the basis of the results given in Table 108 Langley states the following condition for the soaring of an aeroplane 76.2 centimeters long and 12.2 centimeters broad, weighing 500 grams, — that is, a plane one square foot in area, weighing 1.1 pounds. It is supposed to soar in a horizontal direction, with aspect 6.

TABLE 109. — Data for the Soaring of Planes 76.2 × 12.2 cms. weighing 500 Grams, Aspect 6.

| 15                                       | 11.2                | 37            | 86                                   | 623          | 26.5  | 58      |
| 30                                       | 10.6                | 35            | 175                                  | 1268         | 13.0  | 29      |
| 45                                       | 11.2                | 37            | 336                                  | 2434         | 6.8   | 15      |

In general, if  $\rho = \frac{\text{weight}}{\text{area}}$

$$\text{Soaring speed } v = \sqrt{\frac{\rho}{k} \frac{1}{F_a \cos \alpha}}$$

$$\text{Activity per unit of weight} = v \tan \alpha$$

The following data for curved surfaces are due to Wellner (Zeits. für Luftschiffahrt, x., Oct. 1893).

Let the surface be so curved that its intersection with a vertical plane parallel to the line of motion is a parabola whose height is about  $\frac{1}{2}$  the subtending chord, and let the surface be bounded by an elliptic outline symmetrical with the line of motion. Also, let the angle of inclination of the chord of the surface be  $\alpha$ , and the angle between the direction of resultant air pressure and the normal to the direction of motion be  $\beta$ . Then  $\beta < \alpha$ , and the soaring speed is

$$v = \sqrt{\frac{\rho}{k} \frac{1}{F_a \cos \beta}}, \text{ while the activity per unit of weight} = v \tan \beta.$$

The following series of values were obtained from experiments on moving trains and in the wind.

|                                 |      |      |      |      |      |      |
|---------------------------------|------|------|------|------|------|------|
| Angle of inclination $\alpha =$ | -3°  | 0°   | +3°  | 6°   | 9°   | 12°  |
| Inclination factor $F_a =$      | 0.20 | 0.50 | 0.75 | 0.90 | 1.00 | 1.05 |
| $\tan \beta =$                  | 0.01 | 0.02 | 0.03 | 0.04 | 0.10 | 0.17 |

Thus a curved surface shows finite soaring speeds when the angle of inclination  $\alpha$  is zero or even slightly negative. Above  $\alpha = 12^\circ$  curved surfaces rapidly lose any advantage they may have for small inclinations.

SMITHSONIAN TABLES.

TABLE 110. — Friction.

The following table of coefficients of friction  $f$  and its reciprocal  $1/f$ , together with the angle of friction or angle of repose  $\phi$ , is quoted from Rankine's "Applied Mechanics." It was compiled by Rankine from the results of General Morin and other authorities, and is sufficient for all ordinary purposes.

| Material.                                       | $f$       | $1/f$      | $\phi$    |

\* Quoted from a paper by Jenkin and Ewing, "Phil. Trans. R. S." vol. 167. In this paper it is shown that in cases where "static friction" exceeds "kinetic friction" there is a gradual increase of the coefficient of friction as the speed is reduced towards zero.

TABLE 111. — Lubricants.

The best lubricants are in general the following: Low temperatures, light mineral lubricating oils. Very great pressures, slow speeds, graphite, soapstone and other solid lubricants. Heavy pressures, slow speeds, ditto and lard, tallow and other greases. Heavy pressures and high speeds, sperm oil, castor oil, heavy mineral oils. Light pressures, high speeds, sperm, refined petroleum olive, rape, cottonseed. Ordinary machinery, lard oil, tallow oil, heavy mineral oils and the heavier vegetable oils. Steam cylinders, heavy mineral oils, lard, tallow. Watches and delicate mechanisms, clarified sperm, neat's-foot, porpoise, olive and light mineral lubricating oils.

TABLE 112. — Lubricants For Cutting Tools.

| Material.        | Turning.               | Chucking.    | Drilling.    | Tapping<br>Milling. | Reaming. |
|------------------|------------------------|--------------|--------------|---------------------|----------|
| Tool Steel,      | dry or oil             | oil or s. w. | oil          | oil                 | lard oil |
| Soft Steel,      | dry or soda water      | soda water   | oil or s. w. | oil                 | lard oil |
| Wrought iron     | dry or soda water      | soda water   | oil or s. w. | oil                 | lard oil |
| Cast iron, brass | dry                    | dry          | dry          | dry                 | dry      |
| Copper           | dry                    | dry          | dry          | dry                 | dry      |
| Glass            | turpentine or kerosene |              |              |                     | mixture  |

Mixture =  $\frac{1}{3}$  crude petroleum,  $\frac{2}{3}$  lard oil. Oil = sperm or lard.

Tables 111 and 112 quoted from "Friction and Lost Work in Machinery and Mill Work," Thurston, Wiley and Sons.

## VISCOSITY.

The coefficient of viscosity is the tangential force per unit area of one face of a plate of the fluid which is required to keep up unit distortion between the faces. Viscosity is thus measured in terms of the temporary rigidity which it gives to the fluid. Solids may be included in this definition when only that part of the rigidity which is due to varying distortion is considered. One of the most satisfactory methods of measuring the viscosity of fluids is by the observation of the rate of flow of the fluid through a capillary tube, the length of which is great in comparison with its diameter. Poiseuille\* gave the following formula for calculating the viscosity coefficient

in this case:  $\mu = \frac{\pi h r^4 s}{8 \nu l}$ , where  $h$  is the pressure height,  $r$  the radius of the tube,  $s$  the density of

the fluid,  $\nu$  the quantity flowing per unit time, and  $l$  the length of the capillary part of the tube. The liquid is supposed to flow from an upper to a lower reservoir joined by the tube, hence  $h$  and  $l$  are different. The product  $h s$  is the pressure under which the flow takes place. Hagenbach† pointed out that this formula is in error if the velocity of flow is sensible, and suggested a correction which was used in the calculation of his results. The amount to be subtracted from

$h$ , according to Hagenbach, is  $\frac{v^2}{\sqrt{2} \cdot g}$ , where  $g$  is the acceleration due to gravity. Gartenmeister‡

points out an error in this to which his attention had been called by Finkener, and states that the quantity to be subtracted from  $h$  should be simply  $\frac{v^2}{g}$ ; and this formula is used in the reduction

of his observations. Gartenmeister's formula is the most accurate, but all of them nearly agree if the tube be long enough to make the rate of flow very small. None of the formulæ take into account irregularities in the distortion of the fluid near the ends of the tube, but this is probably negligible in all cases here quoted from, although it probably renders the results obtained by the "viscosimeter" commonly used for testing oils useless for our purpose.

The term "specific viscosity" is sometimes used in the headings of the tables; it means the ratio of the viscosity of the fluid under consideration to the viscosity of water at a specified temperature.

The friction of a fluid is proportional to the size of the rubbing surface, to  $\frac{dv}{dx}$ , where  $v$  is the velocity of motion in a direction perpendicular to the rubbing surface, and to a constant known as the viscosity.

| “ “ . . .         | .875     | —                            | —                           | 8  |

\* This table was calculated from the table of fluidities given by Noack (Wied. Ann. vol. 27, p. 217), and shows a maximum for a solution containing about 40 per cent of alcohol. A similar result was obtained for solutions of acetic acid.

† Table 115 is from a paper by Engler in Dingler's "Poly. Jour." vol. 268, p. 76, and Table 116 is from a paper by Lamansky in the same journal, vol. 248, p. 29. The very mixed composition of these oils renders the viscosity a very uncertain quantity, neither the density nor the flashing point being a good guide to viscosity.

‡ The different groups in this table are from different residues.

TABLE 117.  
VISCOSITY.

This table gives some miscellaneous data as to the viscosity of liquids, mostly referring to oils and paraffins. The viscosities are in C. G. S. units.

| Liquid.                         | G. %  | Coefficient of viscosity. | Temp. Cent. ° | Authority.             |
|---------------------------------|-------|---------------------------|---------------|------------------------|

\* Calculated from the formula  $\mu = .017 - .000066t + .0000021t^2 - .0000000025t^3$  (vide Koch, Wied. Ann. vol. 14, p. 1881).

## VISCOSITY.

This table gives the viscosity of a number of liquids together with their temperature variation. The headings are temperatures in Centigrade degrees, and the numbers under them the coefficients of viscosity in C. G. S. units.\*

| Liquid.               | Temperature Centigrade. |        |        |        |        |        |        |        | Reference. |
|-----------------------|-------------------------|--------|--------|--------|--------|--------|--------|--------|------------|

\* Calculated from the specific viscosities given in Landolt & Börnstein's Phys. Chem. Tab.

For inorganic acids, see Solutions.

## VISCOSITY OF SOLUTIONS.

This table is intended to show the effect of change of concentration and change of temperature on the viscosity of solutions of salts in water. The specific viscosity  $\times 100$  is given for two or more densities and for several temperatures in the case of each solution.  $\mu$  stands for specific viscosity, and  $t$  for temperature Centigrade.

| Salt.                             | Percentage by weight of salt in solution. | Density. | $\mu$ |     | $\mu$ |     | $\mu$ |     | $\mu$ |     | Authority. |
|-----------------------------------|---|----------|-------|-----|-------|-----|-------|-----|-------|-----|------------|
|                                   |   |          | $\mu$ | $t$ | $\mu$ | $t$ | $\mu$ | $t$ | $\mu$ | $t$ |            |

\* In the case of solutions of salts it has been found (*vide* Arrhenius, *Zeits. für Phys. Chem.* vol. 1, p. 285) that the specific viscosity can, in many cases, be nearly expressed by the equation  $\mu = \mu_1^n$ , where  $\mu_1$  is the specific viscosity for a normal solution referred to the solvent at the same temperature, and  $n$  the number of grammes molecules in the solution under consideration. The same rule may of course be applied to solutions stated in percentages instead of grammes molecules. The table here given has been compiled from the results of Reyher (*Zeits. für Phys. Chem.* vol. 2, p. 749) and of Wagner (*Zeits. für Phys. Chem.* vol. 5, p. 31) and illustrates this rule. The numbers are all for 25° C.

TABLE 121.—VISCOSITY OF GASES AND VAPORS.

The values of  $\mu$  given in the table are  $10^6$  times the coefficients of viscosity in C. G. S. units.

| Schultze, Ann. der Phys. 1901        | 1.837                  | Gilchrist                      | 1.812                  |

The viscosity of air at 20.2° may be taken as  $1.812 \times 10^{-4}$  within a probable error of less than 0.2 per cent. Its variation with the temperature may be obtained from Holman's formula  $= 1715.50 \times 10^{-7} (1 + 0.00275t - 0.0000034t^2)$ . See Phys. Rev. 1913, p. 124, where full references may be obtained.

## COEFFICIENT OF VISCOSITY OF GASES.

## Temperature Coefficients.

If  $\mu_t$  = the viscosity at  $t^\circ$  C.,  $\mu_0$  = the viscosity at  $0^\circ$ ,  $\alpha$  = the coefficient of expansion,  $\beta$ ,  $\gamma$ , and  $n$  = coefficients independent of  $t$ , then

- (I)  $\mu_t = \mu_0(1 + \alpha t)^n$ . (Meyer, Obermayer, Puluj, Breitenbach.)  
 (II)  $= \mu_0(1 + \beta t)$ . (Meyer, Obermayer.)  
 (III)  $= \mu_0(1 + \alpha t)^{\frac{1}{2}}(1 + \gamma t)^2$ . (Schumann.)

$$(IV) = \mu_0 \frac{1 + \frac{C}{273}}{1 + \frac{C}{T}} \sqrt{1 + \frac{t}{273}} \quad (\text{Sutherland.})$$

## DIFFUSION OF AN AQUEOUS SOLUTION INTO PURE WATER.

If  $k$  is the coefficient of diffusion,  $dS$  the amount of the substance which passes in the time  $dt$ , at the place  $x$ , through  $q$  sq. cm. of a diffusion cylinder under the influence of a drop of concentration  $dc/dx$ , then

$$dS = -kq \frac{dc}{dx} dt.$$

$k$  depends on the temperature and the concentration.  $c$  gives the gram-molecules per liter. The unit of time is a day.

| Substance.                    | $c$ | $t^\circ$ | $k$   | Refer-<br>ence | Substance.                   | $c$   | $t^\circ$ | $k$   | Refer-<br>ence |

\* Taken from Winkelmann's papers (Wied. Ann. vols. 22, 23, and 26). The coefficients for 0° were calculated by Winkelmann on the assumption that the rate of diffusion is proportional to the absolute temperature. According to the investigations of Loschmidt and of Obermeyer the coefficient of diffusion of a gas, or vapor, at 0° C. and a pressure of 76 centimetres of mercury may be calculated from the observed coefficient at another temperature and pressure by the formula  $k_0 = k_T \left(\frac{T_0}{T}\right)^n \frac{p_0}{p}$ , where  $T$  is temperature absolute and  $p$  the pressure of the gas. The exponent  $n$  is found to be about 1.75 for the permanent gases and about 2 for condensable gases. The following are examples: Air—CO<sub>2</sub>,  $n=1.968$ ; CO<sub>2</sub>—N<sub>2</sub>O,  $n=2.05$ ; CO<sub>2</sub>—H,  $n=1.742$ ; CO—O,  $n=1.785$ ; H—O,  $n=1.755$ ; O—N,  $n=1.792$ . Winkelmann's results, as given in the above table, seem to give about 2 for vapors diffusing into air, hydrogen or carbon dioxide.

## DIFFUSION OF GASES, VAPORS, AND METALS.

TABLE 126. — Coefficients of Diffusion for Various Gases and Vapors.\*

**SOLUBILITY OF INORGANIC SALTS IN WATER; VARIATION WITH THE TEMPERATURE.**

The numbers give the number of grams of the *anhydrous* salt soluble in 1000 grams of water at the given temperatures.

| Salt.   | Temperature Centigrade. |      |      |      |       |                   |                   |                   |      |      |      |
|---|-------------------------|------|------|------|-------|-------------------|-------------------|-------------------|------|------|------|

## SOLUBILITY OF SALTS AND GASES IN WATER.

TABLE 128 (concluded) — Solubility of Inorganic Salts in Water; Variation with the Temperature.

The numbers give the number of grams of the *anhydrous* salt soluble in 1000 grams of water at the given temperatures.

| Salt.   | Temperature Centigrade. |     |      |      |      |      |      |      |      |      |      |

TABLE 130. — Solubility of Gases in Water; Variation with the Temperature.

The table gives the weight in grams of the gas which will be absorbed in 1000 grams of water when the partial pressure of the gas plus the vapor pressure of the liquid at the given temperature equals 760 mm.

| Gas.             | 0°     | 10°    | 20°    | 30°    | 40°    | 50°    | 60°    | 70°    | 80°    |

\* This table contains the volumes of different gases, supposed measured at 0° C. and 76 centimeters' pressure, which unit volume of the liquid named will absorb at atmospheric pressure and the temperature stated in the first column. The numbers tabulated are commonly called the absorption coefficients for the gases in water, or in alcohol, at the temperature *t* and under one atmosphere of pressure. The table has been compiled from data published by Bohr & Bock, Bunsen, Carius, Dittmar, Hamberg, Henrick, Pagliano & Emo, Raoult, Schönfeld, Setschenow, and Winkler. The numbers are in many cases averages from several of these authorities.

NOTE.—The effect of increase of pressure is generally to increase the absorption coefficient. The following is approximately the magnitude of the effect in the case of ammonia in alcohol at a temperature of 23° C.:

$$\left\{ \begin{array}{l} P = 45 \text{ cms.} \quad 50 \text{ cms.} \quad 55 \text{ cms.} \quad 60 \text{ cms.} \quad 65 \text{ cms.} \\ \alpha_{23} = 69 \quad \quad \quad 74 \quad \quad \quad 79 \quad \quad \quad 84 \quad \quad \quad 88 \end{array} \right.$$

According to Setschenow the effect of varying the pressure from 45 to 85 centimeters in the case of carbonic acid in water is very small.

SMITHSONIAN TABLES.

\* This determination of the capillary constants of liquids has been the subject of many careful experiments, but the results of the different experimenters, and even of the same observer when the method of measurement is changed, do not agree well together. The values here quoted can only be taken as approximations to the actual values for the liquids in a state of purity in contact with pure air. In the case of water the values given by Lord Rayleigh from the wave length of ripples (Phil. Mag. 1890) and by Hall from direct measurement of the tension of a flat film (Phil. Mag. 1893) have been preferred, and the temperature correction has been taken as 0.141 dyne per degree centigrade. The values for alcohol were derived from the experiments of Hall above referred to and the experiments on the effect of temperature made by Timberg (Wied. Ann. vol. 30).

† The authority for a few of the other values given is quoted, but they are for the most part average values derived from a large number of results published by different experimenters.

‡ From Volkmann (Wied. Ann. vol. 17, p. 353).

**TABLE 138. — Tension of Soap Films.**

Elaborate measurements of the thickness of soap films have been made by Reinold and Rucker.¶ They find that a film of oleate of soda solution containing 1 of soap to 70 of water, and having 3 per cent of  $\text{KNO}_3$  added to increase electrical conductivity, breaks at a thickness varying between 7.2 and 14.5 micro-millimeters, the average being 12.1 micro-millimeters. The film becomes black and apparently of nearly uniform thickness round the point where fracture begins. Outside the black patch there is the usual display of colors, and the thickness at these parts may be estimated from the colors of thin plates and the refractive index of the solution (*vide* Newton's rings, Table 222).

When the percentage of  $\text{KNO}_3$  is diminished, the thickness of the black patch increases. For example,

$$\text{KNO}_3 = 3 \quad 1 \quad 0.5 \quad 0.0$$

Thickness = 12.4 13.5 14.5 22.1 micro-mm.

A similar variation was found in the other soaps.

It was also found that diminishing the proportion of soap in the solution, there being

- no  $\text{KNO}_3$  dissolved, increased the thickness of the film.
- 1 part soap to 30 of water gave thickness 21.6 micro-mm.
- 1 part soap to 40 of water gave thickness 22.1 micro-mm.
- 1 part soap to 60 of water gave thickness 27.7 micro-mm.
- 1 part soap to 80 of water gave thickness 29.3 micro-mm.

\* This table of tensions at the surface separating the liquid named in the first column and air, water or mercury as stated at the head of the last three columns, is from Quincke's experiments (Pogg. Ann. vol. 130, and Phil. Mag. 1871). The numbers given are the equivalent in dynes per centimeter of those obtained by Worthington from Quincke's results (Phil. Mag. vol. 20, 1885) with the exception of those in brackets, which were not corrected by Worthington; they are probably somewhat too high, for the reason stated by Worthington. The temperature was about 20° C.

† Quincke, "Pogg. Ann." vol. 135, p. 661.

‡ It will be observed that the value here given on the authority of Quincke is much higher than his subsequent measurements, as quoted above, give.

¶ "Proc. Roy. Soc." 1877, and "Phil. Trans. Roy. Soc." 1881, 1883, and 1893.

NOTE. — Quincke points out that substances may be divided into groups in each of which the ratio of the surface tension to the density is nearly constant. Thus, if this ratio for mercury be taken as unit, the ratio for the bromides and iodides is about a half; that of the nitrates, chlorides, sugars, and fats, as well as the metals, lead, bismuth, and antimony, about 1; that of water, the carbonates, sulphates, and probably phosphates, and the metals platinum, gold, silver, cadmium, tin, and copper, 2; that of zinc, iron, and palladium, 3; and that of sodium, 6.

## VAPOR PRESSURES.

The vapor pressures here tabulated have been taken, with one exception, from Regnault's results. The vapor pressure of Pictet's fluid is given on his own authority. The pressures are in centimeters of mercury.

## VAPOR PRESSURE OF SOLUTIONS OF SALTS IN WATER.\*

The first column gives the chemical formula of the salt. The headings of the other columns give the number of gram-molecules of the salt in a liter of water. The numbers in these columns give the lowering of the vapor pressure produced by the salt at the temperature of boiling water under 76 centimeters barometric pressure.

SMITHSONIAN TABLES.

PRESSURE OF AQUEOUS VAPOR IN THE ATMOSPHERE.

This table gives the vapor pressure corresponding to various values of the difference  $t - t_1$  between the readings of dry and wet bulb thermometers and the temperature  $t_1$  of the wet bulb thermometer. The differences  $t - t_1$  are given by two-degree steps in the top line, and  $t_1$  by degrees in the first column. Temperatures in Centigrade degrees and Regnault's vapor pressures in millimeters of mercury are used throughout the table. The table was calculated for barometric pressure  $B$  equal to 76 centimeters, and a correction is given for each centimeter at the top of the columns.\* Ventilating velocity of wet thermometer about 3 meters per second.

| $t_1$                                 | $t - t_1 = 0$ | 2     | 4     | 6     | 8     | 10    | 12    | 14    | 16    | 18    | 20    | Difference per 1° of $t - t_1$ |
|---------------------------------------|---------------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|--------------------------------|

*Example.*  
 $t - t_1 = 7.2$   
 $t_1 = 10.0$   
 $B = 74.5$   
 Tabular number =  $6.12 - 6 \times .101 = 5.51$   
 Correction for  $B = 1.5 \times .048 \dots = .07$   
 Hence we get  $p \dots = 5.58$

\* The table was calculated from the formula  $p = p_1 - 0.00066 B (t - t_1) (1 + 0.00115 t_1)$  (Ferrel, Annual Report U. S. Chief Signal Officer, 1886, App. 24).  
 † When  $B$  is less than 76 the correction is to be added, and when  $B$  is greater than 76 it is to be subtracted.

The first column of this table gives the temperatures of the wet-bulb thermometer, and the top line the difference the table. The dew-points were computed for a barometric pressure of 76 centimeters. When the barometer differs and the resulting number added to or subtracted from the tabular number according as the barometer is below or

| $t_1$   | $t - t_1 = 1$ | 2     | 3     | 4     | 5     | 6     | 7     | 8     |

\* Abridged from Table 45 of "Smithsonian Meteorological Tables."

VALUES OF  $0.378e$ .\*

This table gives the humidity term  $0.378e$ , which occurs in the equation  $\delta = \delta_0 \frac{h}{760} = \delta_0 \frac{B - 0.378e}{760}$  for the calculation of the density of air containing aqueous vapor at pressure  $e$ ;  $\delta_0$  is the density of dry air at normal temperature and barometric pressure,  $B$  the observed barometric pressure, and  $h = B - 0.378e$ , the pressure corrected for humidity. For values of  $\frac{h}{760}$  see Table 154. Temperatures are in degrees Centigrade, and pressures in millimeters of mercury.

\* This table is quoted from "Smithsonian Meteorological Tables," p. 225.

RELATIVE DENSITY OF MOIST AIR FOR DIFFERENT PRESSURES AND HUMIDITIES.

TABLE 154. — Values of  $\frac{h}{760}$  from  $h = 1$  to  $h = 9$ , for the Computation of Different Values of the Ratio of Actual to Normal Barometric Pressure.

This gives the density of moist air at pressure  $h$  in terms of the density of the same air at normal atmosphere pressure. When air contains moisture, as is usually the case with the atmosphere, we have the following equation for pressure term:  $h = B - 0.37e$ , where  $e$  is the vapor pressure, and  $B$  the corrected barometric pressure. When the necessary psychrometric observations are made the value of  $e$  may be taken from Table 150, and then  $0.37e$  from Table 153, or the dew-point may be found and the value of  $0.37e$  taken from Table 153.

| $h$ | $\frac{h}{760}$ |
|-----|-----------------|
| 1   | 0.0013158       |
| 2   | .0026316        |
| 3   | .0039474        |
| 4   | 0.0052632       |
| 5   | .0065789        |
| 6   | .0078947        |
| 7   | 0.0092105       |
| 8   | .0105263        |
| 9   | .0118421        |

EXAMPLES OF USE OF THE TABLE.

To find the value of  $\frac{h}{760}$  when  $h = 754.3$

|              |       |                |
|--------------|-------|----------------|
| $h = 700$    | gives | .92105         |
| 50           | "     | .065789        |
| 4            | "     | .005263        |
| .3           | "     | .000395        |
| <u>754.3</u> |       | <u>.992497</u> |

To find the value of  $\frac{h}{760}$  when  $h = 5.73$

|             |       |                 |
|-------------|-------|-----------------|
| $h = 5$     | gives | .0065789        |
| .7          | "     | .0003210        |
| .03         | "     | .0000395        |
| <u>5.73</u> |       | <u>.0075394</u> |

TABLE 155. — Values of the logarithms of  $\frac{h}{760}$  for values of  $h$  between 80 and 340.

Values from 8 to 80 may be got by subtracting 1 from the characteristic, and from 0.8 to 8 by subtracting 2 from the characteristic, and so on.

| $h$ | Values of $\log \frac{h}{760}$ . |                 |                 |                 |                 |                 |                 |                 |                 |                 |
|-----|----------------------------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|

TABLE 156.  
VOLUME OF CASES.

Values of  $1 + .00367 t$ .

The quantity  $1 + .00367 t$  gives for a gas the volume at  $t^\circ$  when the pressure is kept constant, or the pressure at  $t^\circ$  when the volume is kept constant, in terms of the volume or the pressure at  $0^\circ$ .

- (a) This part of the table gives the values of  $1 + .00367 t$  for values of  $t$  between  $0^\circ$  and  $10^\circ$  C. by tenths of a degree.  
 (b) This part gives the values of  $1 + .00367 t$  for values of  $t$  between  $-90^\circ$  and  $+199^\circ$  C. by  $10^\circ$  steps.

These two parts serve to give any intermediate value to one tenth of a degree by a simple computation as follows:— In the (b) table find the number corresponding to the nearest lower temperature, and to this number add the decimal part of the number in the (a) table which corresponds to the difference between the nearest temperature in the (b) table and the actual temperature. For example, let the temperature be  $682^\circ.2$ :

We have for 680 in table (b) the number . . . . 3.49560  
 And for .2 in table (a) the decimal . . . . . .00807  
 Hence the number for 682.2 is . . . . . 3.50367

- (c) This part gives the logarithms of  $1 + .00367 t$  for values of  $t$  between  $-49^\circ$  and  $+399^\circ$  C. by degrees.  
 (d) This part gives the logarithms of  $1 + .00367 t$  for values of  $t$  between  $400^\circ$  and  $1990^\circ$  C. by  $10^\circ$  steps.  
 (a) Values of  $1 + .00367 t$  for Values of  $t$  between  $0^\circ$  and  $10^\circ$  C. by Tenths of a Degree.

SMITHSONIAN TABLES.

## DETERMINATION OF HEIGHTS BY THE BAROMETER.

$$\text{Formula of Babinet: } Z = C \frac{B_0 - B}{B_0 + B}$$

$$C \text{ (in feet)} = 52494 \left[ 1 + \frac{t_0 + t - 64}{900} \right] \text{ English measures.}$$

$$C \text{ (in meters)} = 16000 \left[ 1 + \frac{2(t_0 + t)}{1000} \right] \text{ metric measures.}$$

In which  $Z$  = difference of height of two stations in feet or meters.

$B_0, B$  = barometric readings at the lower and upper stations respectively, corrected for all sources of instrumental error.

$t_0, t$  = air temperatures at the lower and upper stations respectively.

Values of  $C$ .

| ENGLISH MEASURES.        |       |         | METRIC MEASURES.         |         |         |

\* Pressures in inches of mercury

The values at the lower temperatures are perhaps  $\frac{1}{2}\%$  too low. Table (b) is based on more recent data (1913).

| 6438.4696 | (accepted primary standard) Benoit, Fabry, Perot, C. R. 144, 1082, 1907.   |

TABLE 160. — International Secondary Standards. Iron Arc Lines.

Adopted as secondary standards at the International Union for Coöperation in Solar Research (transactions, 1910). Means of measures of Fabry-Buisson (1), Pfund (2), and Eversheim (3). Referred to primary standard = Cd. line,  $\lambda = 6438.4696$  Ångströms (serving to define an Ångström). 760 mm., 15° C. Iron rods, 7 mm. diam. length of arc, 6 mm.; 6 amp. for  $\lambda$  greater than 4000 Ångströms, 4 amp. for lesser wave-lengths; continuous current, + pole above the —, 220 volts; source of light, 2 mm. at arc's center. Lines adopted in 1910.

SMITHSONIAN TABLES.

STANDARD SOLAR WAVE-LENGTHS. ROWLAND'S VALUES.

Wave-lengths are in Ångström units ( $10^{-7}$  mm.), in air at 20° C and 76 cm. of mercury pressure. The intensities run from 1, just clearly visible on the map, to 1000 for the H and K lines; below 1 in order of faintness to 0000 as the lines are more and more difficult to see. This table contains only the lines above 5.

N indicates a line not clearly defined, probably an undissolved multiple line; s, a faded appearing line; d, a double. In the "substance" column, where two or more elements are given, the line is compound; the order in which they are given indicates the portion of the line due to each element; when the solar line is too strong to be due wholly to the element given, it is represented, -Fe, for example; when commas separate the elements instead of a dash, the metallic lines coincide with the same part of the solar line, Fe, Cr, for example.

Capital letters next the wave-length numbers are the ordinary designations of the lines. A indicates atmospheric lines, (wv), due to water vapor, (O), due to Oxygen.

| Wave-length. | Substance. | Inten-sity. | Wave-length. | Substance. | Inten-sity. | Wave-length. | Sub-stance. | Inten-sity. |

Corrections to reduce Rowland's wave-lengths to standards of Table 160 (the accepted standards, 1913). Temperature 15° C, pressure 760 mm.

The differences "(Fabry-Buisson-arc-iron) - (Rowland-solar-iron)" lines were plotted, a smooth curve drawn, and the following values obtained:

| Wave-length | 3000. | 3100. | 3200. | 3300. | 3400. | 3500. | 3600. | 3700. |
|-------------|-------|-------|-------|-------|-------|-------|-------|-------|
| Correction  | -.106 | -.115 | -.124 | -.137 | -.148 | -.154 | -.155 | -.140 |

H. A. Rowland, "A preliminary table of solar-spectrum wave-lengths," Astrophysical Journal, 1-6, 1895-1897.

SMITHSONIAN TABLES.

## TERTIARY STANDARD WAVE-LENGTHS. IRON ARC LINES.

For arc conditions see Table 160, p. 172. For lines of group *c* class 5 for best results the slit should be at right angles to the arc at its middle point and the current should be reversed several times during the exposure.

\* Measures of Burns.

† Means of St. John and Burns.

‡ Means of St. John and Goos. Others are means of measures by all three. References: St. John and Ware, *Astrophysical Journal*, 36, 1912; 38, 1913; Burns, *Z. f. wissen. Photog.*, 12, p. 207, 1913, *J. de Phys.*, 1913, and unpublished data; Goos, *Astrophysical Journal*, 35, 1912; 37, 1913. The lines in the table have been selected from the many given in these references with a view to equal distribution and where possible of classes *a* and *b*.

For class and pressure shifts see Gale and Adams, *Astrophysical Journal*, 35, p. 10, 1912. Class *a*: "This involves the well-known flame lines (de Wetteville, *Phil. Trans.* A 204, p. 139, 1904), i.e. the lines relatively strengthened in low-temperature sources, such as the flame of the arc, the low-current arc, and the electric furnace. (*Astrophysical Journal*, 24, p. 185, 1906, 30, p. 86, 1909, 34, p. 37, 1911, 35, p. 185, 1912.) The lines of this group in the yellow-green show small but definite pressure displacements, the mean being 0.0036 Ångström per atmosphere in the arc." Class *b*: "To this group many lines belong; in fact all the lines of moderate displacement under pressure are assigned to it for the present. These are bright and symmetrically widened under pressure, and show mean pressure displacements of 0.009 Ångström per atmosphere for the lines in the region  $\lambda$  5975-6678 according to Gale and Adams. Group *c* contains lines showing much larger displacements. The numbers in the class column have the following meaning: 1, symmetrically reversed; 2, unsymmetrically reversed; 3, remain bright and fairly narrow under pressure; 4, remain bright and symmetrical under pressure but become wide and diffuse; 5, remain bright and are widened very unsymmetrically toward the red under pressure."

For further measures in International units see Kayser, *Bericht über den gegenwärtigen Stand der Wellenlängenmessungen*, International Union for Coöperation in Solar Research, 1913. For further spectroscopic data see Kayser's *Handbuch der Spectroscopie*.

## WAVE-LENGTHS OF FRAUNHOFER LINES.

For convenience of reference the values of the wave-lengths corresponding to the Fraunhofer lines usually designated by the letters in the column headed "index letters," are here tabulated separately. The values are in ten millionths of a millimeter, on the supposition that the D line value is 5896.155. The table is for the most part taken from Rowland's table of standard wave-lengths.

| Index Letter.        | Line due to— | Wave-length in centimeters $\times 10^8$ . | Index Letter.       | Line due to— | Wave-length in centimeters $\times 10^8$ . |
|----------------------|--------------|--|---------------------|--------------|--|

\* The two lines here given for A are stated by Rowland to be: the first, a line "beginning at the head of A, outside edge;" the second, a "single line beginning at the tail of A."

† The principal line in the head of B.

‡ Chief line in the α group.

See Table 163, Rowland's Solar Wave-lengths (foot of page) for correction to reduce these values to standard system of wave-lengths, Table 160.

SMITHSONIAN TABLES.

TABLE 166. — Photometric Standards.

No primary photometric standard has been generally adopted by the various governments. In Germany the Hefner lamp is most used; in England the Pentane lamp and sperm candles are used; in France the Carcel lamp is preferred; in America the Pentane and Hefner lamps are used to some extent, but candles are more largely employed in gas photometry. For the photometry of electric lamps, and generally in accurate photometric work, electric lamps, standardized at a national standardizing institution, are commonly employed.

The "International candle" is the name recently employed to designate the value of the candle as maintained by cooperative effort between the national laboratories of England, France, and America; and the value of various photometric units in terms of this international candle is given in the following table (taken from Circular No. 15 of the Bureau of Standards).

- 1 International Candle = 1 Pentane Candle.
- 1 International Candle = 1 Bougie Decimale.
- 1 International Candle = 1 American Candle.
- 1 International Candle = 1.11 Hefner Unit.
- 1 International Candle = 0.104 Carcel Unit.

Therefore 1 Hefner Unit = 0.90 International Candle.

The values of the flame standards most commonly used are as follows:

1. Standard Pentane Lamp, burning pentane . . . . . 10.0 candles.
2. Standard Hefner Lamp, burning amyl acetate . . . . . 0.9 candles.
3. Standard Carcel Lamp, burning colza oil . . . . . 9.6 candles.
4. Standard English Sperm Candle, approximately . . . . . 1.0 candles.

Slight differences in candle power are found in different lamps, even when made as accurately as possible to the same specifications. Hence these so-called primary standards should be themselves standardized.

Paper by Prof. J. M. Bryant and Mr. H. G. Hake, Engineering Experiment Station, University of Illinois.

SMITHSONIAN TABLES.

**SENSITIVENESS OF THE EYE TO RADIATION.**

(Compiled from Nutting, Bulletin of the Bureau of Standards.)

Radiation is easily visible to most eyes from 0.330 $\mu$  in the violet to 0.770 $\mu$  in the red. At low intensities approaching threshold values (rod vision) the maximum of spectral sensibility lies in the green at about 0.510 $\mu$  for 90% of all persons. At higher intensities with the establishment of cone vision the maximum shifts towards the yellow at least as far as 0.560 $\mu$ .

**TABLE 170. — Variation of the Sensitiveness of the Eye with the Wave-length at Low Intensities (near Threshold Values). König.**

**TABLE 171. — Variation of Sensitiveness to Radiation of Greater Intensities.**

The sensibility is approximately proportional to the intensity over a wide range. The ratio of optical- to radiation-intensity increases more rapidly for the red than for the blue or green (Purkinje phenomenon).

The intensity is given for the spectrum at 0.535 $\mu$  (green).

The sensibility to small differences in intensity is independent of the intensity (Fechner's law). About 0.016 for moderate intensities. Greater for extreme values. It is independent of wave-length, extremes excepted (König's law).

Sensibility to slight differences in wave-length has two pronounced maxima (one in the yellow, one in the green) and two slight maxima (extreme blue, extreme red).

The visual sensation as a function of the time approaches a constant value with the lapse of time. With blue light there seems to be a pronounced maximum at 0.07 sec., with red a slight one at 0.12 seconds, with green the sensation rises steadily to its final value. For lower intensities these max. occur later.

An intensity of 500 metre-candles is about that on a horizontal plane on a cloudy day.

TABLE 173.—The Solar Constant.

Solar constant (amount of energy falling at normal incidence on one square centimeter per minute on body at earth's mean distance) = 1.932 calories = mean 696 determinations 1902-12. Apparently subject to variations, usually within the range of 7 per cent, and occurring irregularly in periods of a week or ten days.

Computed effective temperature of the sun: from form of black-body curves, 6000° to 7000° Absolute; from  $\lambda_{max}$ . = 2930 and max. = 0.470 $\mu$ , 6230°; from total radiation,  $J = 76.8 \times 10^{-12} \times T^4$ , 5830°.

TABLE 174.—Solar spectrum energy (arbitrary units) and its transmission by the earth's atmosphere.

Values computed from  $e_m = e_0 a^m$ , where  $e_m$  is the intensity of solar energy after transmission through a mass of air  $m$ ;  $m$  is unity when the sun is in the zenith, and approximately = sec. zenith distance for other positions (see table 180);  $e_0$  = the energy which would have been observed had there been no absorbing atmosphere;  $a$  is the fractional amount observed when the sun is in the zenith.

ATMOSPHERIC TRANSPARENCY AND SOLAR RADIATION.

TABLE 177.—Transmission of Radiation Through Moist and Dry Air.

This table gives the wave-length,  $\lambda$ ;  $a$  the transmission of radiation by dry air above Mount Wilson (altitude = 1730 m. barometer, 620 mm.) for a body in the zenith; finally a correction factor,  $a_w$ , due to such a quantity of aqueous vapor in the air that if condensed it would form a layer 1 cm. thick. Except in the bands of selective absorption due to the air,  $a$  agrees very closely with what would be expected from purely molecular scattering.  $a_w$  is very much smaller than would be correspondingly expected, due possibly to the formation of ions by the ultra-violet light from the sun. The transmission varies from day to day. However, values for clear days computed as follows agree within a per cent or two of those observed when the altitude of the place is such that the effect due to dust may be neglected, e. g. for altitudes greater than 1000 meters. If  $B = \frac{B}{a_w}$  the barometric pressure in mm.,  $w$ , the amount of precipitable water in cm., then  $a_B = a_w^{0.20} \frac{B}{w}$ .  $w$  is best determined spectroscopically (Astrophysical Journal, 35, p. 149, 1912, 37, p. 359, 1913) otherwise by formula derived from Hann,  $w = 2.3e_w 10^{-\frac{22300}{h}}$ ,  $e_w$  being the vapor pressure in cm. at the station,  $h$ , the altitude in meters.

TABLE 180.—Air Masses.

See Table 174 for definition. Besides values derived from the pure secant formula, the table contains those derived from various other more complex formula, taking into account the curvature of the earth, refraction, etc. The most recent is that of Bemporad.

\* Weegmann gives  $\mu_D = 1.59668 - .000518 t$ . Knops gives  $\mu_F = 1.61500 - .00056 t$ .† Weegmann gives  $\mu_D = 1.51474 - .000665 t$ . Knops gives  $\mu_D = 1.51399 - .000644 t$ .‡ Willner gives  $\mu_C = 1.63407 - .00078 t$ ;  $\mu_F = 1.66908 - .00082 t$ ;  $\mu_H = 1.69215 - .00085 t$ .§ Dufet gives  $\mu_D = 1.33397 - 10^{-7}(125 t + 20.6 t^2 - .000435 t^3 - .00115 t^4)$  between 0° and 50°; and nearly the same variation with temperature was found by Ruhlmann, namely,  $\mu_D = 1.33373 - 10^{-7}(20.14 t^2 + .000494 t^3)$ .

SMITHSONIAN TABLES.

INDEX OF REFRACTION.

Indices of Refraction of Gases and Vapors.

A formula was given by Biot and Arago expressing the dependence of the index of refraction of a gas on pressure and temperature. More recent experiments confirm their conclusions. The formula is  $n_t - 1 = \frac{n_0 - 1}{1 + at} \frac{p}{760}$ , where  $n_t$  is the index of refraction for temperature  $t$ ,  $n_0$  for temperature zero,  $a$  the coefficient of expansion of the gas with temperature, and  $p$  the pressure of the gas in millimeters of mercury.

First 4, Cuthbertsons; the rest, Koch, 1909.

(b) The following are compiled mostly from a table published by Brühl (Zeits. für Phys. Chem. vol. 7, pp. 25-27). The numbers are from the results of experiments by Biot and Arago, Dulong, Jamin, Ketteler, Lorenz, Mascart, Chappius, Rayleigh, and Rivière and Prytz. When the number given rests on the authority of one observer the name of that observer is given. The values are for 0° Centigrade and 760 mm. pressure.

**MEDIA FOR DETERMINATIONS OF REFRACTIVE INDICES WITH  
THE MICROSCOPE.**

**TABLE 201. — Liquids,  $n_D$  (0.589 $\mu$ ) = 1.74 to 1.87.**

In 100 parts of methylene iodide at 20° C. the number of parts of the various substances indicated in the following table can be dissolved, forming saturated solutions having the permanent refractive indices specified. When ready for use the liquids can be mixed by means of a dropper to give intermediate refractions. Commercial iodoform (CHI<sub>3</sub>) powder is not suitable, but crystals from a solution of the powder in ether may be used, or the crystallized product may be bought. A fragment of tin in the liquids containing the SnI<sub>4</sub> will prevent discoloration.

| CHI <sub>3</sub> , | SnI <sub>4</sub> , | AsI <sub>3</sub> , | SbI <sub>3</sub> , | S. | $n_{Dn}$ at 20°. |

**TABLE 202. — Resin-like Substances,  $n_D$  (0.589 $\mu$ ) = 1.68 to 2.10.**

Piperine, one of the least expensive of the alkaloids, can be obtained very pure in straw-colored crystals. When melted it dissolves the tri-iodides of arsenic and antimony very freely. The solutions are fluid at slightly above 100° and when cold, resin-like. A solution containing 3 parts antimony iodide to one part of arsenic iodide with varying proportions of piperine is easier to manipulate than one containing either iodide alone. The following table gives the necessary data concerning the composition and refractive indices for sodium light. In preparing, the constituents, in powder of about 1 mm. grain, should be weighed out and then fused *over*, not *in*, a low flame. Three-inch test tubes are suitable.

| Per cent Iodides.   | 00.   | 10.   | 20.   | 30.   | 40.   | 50.   | 60.   | 70.   | 80.   |
|---------------------|-------|-------|-------|-------|-------|-------|-------|-------|-------|
| Index of refraction | 1.683 | 1.700 | 1.725 | 1.756 | 1.794 | 1.840 | 1.897 | 1.968 | 2.050 |

**TABLE 203. — Permanent Standard Resinous Media,  $n_D$  (0.589 $\mu$ ) = 1.546 to 1.682.**

Any proportions of piperine and rosin form a homogeneous fusion which cools to a transparent resinous mass. The following table shows the refractive indices of various mixtures. On account of the strong dispersion of piperine the refractive indices of minerals apparently matched with those of mixtures rich in this constituent are 0.005 to 0.01 too low. To correct this error a screen made of a thin film of 7 per cent antimony iodide and 93 per cent piperine should be used over the eye-piece. Any amber-colored rosin in lumps is suitable.

| Per cent Rosin.     | 00.   | 10.   | 20.   | 30.   | 40.   | 50.   | 60.   | 70.   | 80.   | 90.   | 100.  |

OPTICAL CONSTANTS OF METALS.

TABLE 204.

Two constants are required to characterize a metal optically, the refractive index,  $n$ , and the absorption index,  $k$ , the latter of which has the following significance: the amplitude of a wave after travelling one wave-length,  $\lambda^1$  measured in the metal, is reduced in the ratio  $1 : e^{-2\pi k}$  or for any distance  $d$ ,  $1 : e^{-\frac{2\pi dk}{\lambda^1}}$ ; for the same wave-length measured in air this ratio becomes  $1 : e^{-\frac{2\pi dnk}{\lambda^1}}$ .  $nk$  is sometimes called the extinction coefficient. Plane polarized light reflected from a polished metal surface is in general elliptically polarized because of the relative change in phase between the two rectangular components vibrating in and perpendicular to the plane of incidence. For a certain angle,  $\phi$  (principal incidence) the change is  $90^\circ$  and if the plane polarized incident beam has a certain azimuth  $\bar{\psi}$  (Principal azimuth) circularly polarized light results. Approximately, (Drude, Annalen der Physik, 36, p. 546, 1889),

$$k = \tan 2\bar{\psi} (1 - \cot^2 \phi) \text{ and } n = \frac{\sin \bar{\phi} \tan \bar{\phi}}{(1 + k^2)^{\frac{1}{2}}} (1 + \frac{1}{2} \cot^2 \bar{\phi}).$$

For rougher approximations the factor in parentheses may be omitted. R = computed percentage reflection.

TABLE 205.

(The points have been so selected that a smooth curve drawn through them very closely indicates the characteristics of the metal.)

Coblentz, Bulletin Bureau of Standards, 2, p. 457, 1906, 7, p. 197, 1911. The surfaces of some of the samples were not perfect so that the corresponding values have less weight. The methods for polishing the various metals are described in the original articles.

SMITHSONIAN TABLES.

According to Fresnel the amount of light reflected by the surface of a transparent medium  $= \frac{1}{2}(A + B) = \frac{1}{2} \left\{ \frac{\sin^2(i - r)}{\sin^2(i + r)} + \frac{\tan^2(i - r)}{\tan^2(i + r)} \right\}$ ;  $A$  is the amount polarized in the plane of incidence;  $B$  is that polarized perpendicular to this;  $i$  and  $r$  are the angles of incidence and refraction.

Angle of total polarization  $= 57^\circ 10'.3$ ,  $A = 16.99$ .

\* This column gives the degree of polarization. † Columns 5 and 6 furnish a means of determining  $A$  and  $B$  for other values of  $n$ . They represent the change in these quantities for a change of  $n$  of 0.01.

Taken from E. C. Pickering's "Applications of Fresnel's Formula for the Reflection of Light."

TABLES 211-212.  
REFLECTION OF METALS.

TABLE 211. — Perpendicular Incidence and Reflection.

The numbers give the per cents of the incident radiation reflected.

\*Not monochromatic (max.) means from Coblenz, J. Franklin Inst. 1912. Bulletin Bureau of Standards, 9, p. 283, 1912, contains many other materials.

TRANSMISSIBILITY FOR RADIATION OF JENA GLASSES.

TABLE 213.

Coefficients,  $a$ , in the formula  $I_t = I_0 e^{-at}$ , where  $I_0$  is the intensity before, and  $I_t$  after, transmission through the thickness  $t$ , expressed in centimeters. Deduced from observations by Müller, Vogel, and Rubens as quoted in Hovestadt's Jena Glass (English translation).

## TRANSMISSIBILITY FOR RADIATION.

Transmissibility of the Various Substances of Tables 166 to 175.

**Alum**: Ordinary alum (crystal) absorbs the infra-red.Metallic reflection at  $9.05\mu$  and  $30$  to  $40\mu$ .**Rock-salt**: Rubens and Trowbridge (Wied. Ann. 65, 1898) give the following transparencies for a 1 cm. thick plate in %:

|           |      |      |      |      |      |      |      |      |      |     |      |            |
|-----------|------|------|------|------|------|------|------|------|------|-----|------|------------|
| $\lambda$ | 9    | 10   | 12   | 13   | 14   | 15   | 16   | 17   | 18   | 19  | 20.7 | 23.7 $\mu$ |
| %         | 99.5 | 99.5 | 99.3 | 97.6 | 93.1 | 84.6 | 66.1 | 51.6 | 27.5 | 9.6 | 0.6  | 0.         |

Pflüger (Phys. Zt. 5, 1904) gives the following for the ultra-violet, same thickness:  $280\mu$ , 95.5%;  $231$ , 86%;  $210$ , 77%;  $186$ , 70%.Metallic reflection at  $0.110\mu$ ,  $0.156$ ,  $51.2$ , and  $87\mu$ .**Sylvine**: Transparency of a 1 cm. thick plate (Trowbridge, Wied. Ann. 60, 1897).

|           |      |      |      |      |      |      |      |      |     |     |     |      |            |
|-----------|------|------|------|------|------|------|------|------|-----|-----|-----|------|------------|
| $\lambda$ | 9    | 10   | 11   | 12   | 13   | 14   | 15   | 16   | 17  | 18  | 19  | 20.7 | 23.7 $\mu$ |
| %         | 100. | 98.8 | 99.0 | 99.5 | 99.5 | 97.5 | 95.4 | 93.6 | 92. | 86. | 76. | 58.  | 15.        |

Metallic reflection at  $0.114\mu$ ,  $0.161$ ,  $61.1$ ,  $100$ .**Fluorite**: Very transparent for the ultra-violet nearly to  $0.1\mu$ .

Rubens and Trowbridge give the following for a 1 cm. plate (Wied. Ann. 60, 1897):

|           |        |      |      |     |         |
|-----------|--------|------|------|-----|---------|
| $\lambda$ | $8\mu$ | 9    | 10   | 11  | $12\mu$ |
| %         | 84.4   | 54.3 | 16.4 | 1.0 | 0       |

Metallic reflection at  $24\mu$ ,  $31.6$ ,  $40\mu$ .**Iceland Spar**: Merritt (Wied. Ann. 55, 1895) gives the following values of  $k$  in the formula  $i = i_0 e^{-kd}$  ( $d$  in cm.):

For the ordinary ray:

|           |      |      |      |      |      |      |      |      |      |      |            |
|-----------|------|------|------|------|------|------|------|------|------|------|------------|
| $\lambda$ | 1.02 | 1.45 | 1.72 | 2.07 | 2.11 | 2.30 | 2.44 | 2.53 | 2.60 | 2.65 | 2.74 $\mu$ |
| $k$       | 0.0  | 0.0  | 0.03 | 0.13 | 0.74 | 1.92 | 3.00 | 1.92 | 1.21 | 1.74 | 2.36       |

|           |      |      |      |      |      |      |      |      |          |      |      |            |
|-----------|------|------|------|------|------|------|------|------|----------|------|------|------------|
| $\lambda$ | 2.83 | 2.90 | 2.95 | 3.04 | 3.30 | 3.47 | 3.62 | 3.80 | 3.98     | 4.35 | 4.52 | 4.83 $\mu$ |
| $k$       | 1.32 | 0.70 | 1.80 | 4.71 | 22.7 | 19.4 | 9.6  | 18.6 | $\infty$ | 6.6  | 14.3 | 6.1        |

For the extraordinary ray:

|           |      |      |      |      |      |      |      |      |      |      |            |
|-----------|------|------|------|------|------|------|------|------|------|------|------------|
| $\lambda$ | 2.49 | 2.87 | 3.00 | 3.28 | 3.38 | 3.59 | 3.76 | 3.90 | 4.02 | 4.41 | 4.67 $\mu$ |
| $k$       | 0.14 | 0.08 | 0.43 | 1.32 | 0.89 | 1.79 | 2.04 | 1.17 | 0.89 | 1.07 | 2.40       |

|           |      |      |      |            |
|-----------|------|------|------|------------|
| $\lambda$ | 4.91 | 5.04 | 5.34 | 5.50 $\mu$ |
| $k$       | 1.25 | 2.13 | 4.41 | 12.8       |

**Quartz**: Very transparent to the ultra-violet: Pflüger gets the following transmission values for a plate 1 cm. thick: at  $0.222\mu$ , 94.2%;  $0.214$ , 92;  $0.203$ , 83.6;  $0.186$ , 67.2%.Merritt (Wied. Ann. 55, 1895) gives the following values for  $k$  (see formula under Iceland Spar):

For the ordinary ray:

|           |      |      |      |      |      |      |      |      |      |      |            |
|-----------|------|------|------|------|------|------|------|------|------|------|------------|
| $\lambda$ | 2.72 | 2.83 | 2.95 | 3.07 | 3.17 | 3.38 | 3.67 | 3.82 | 3.96 | 4.12 | 4.50 $\mu$ |
| $k$       | 0.20 | 0.47 | 0.57 | 0.31 | 0.20 | 0.15 | 1.26 | 1.61 | 2.04 | 3.41 | 7.30       |

For the extraordinary ray:

|           |      |      |      |      |      |      |      |      |      |      |      |      |            |
|-----------|------|------|------|------|------|------|------|------|------|------|------|------|------------|
| $\lambda$ | 2.74 | 2.89 | 3.00 | 3.08 | 3.26 | 3.43 | 3.52 | 3.59 | 3.64 | 3.74 | 3.91 | 4.19 | 4.36 $\mu$ |
| $k$       | 0.0  | 0.11 | 0.33 | 0.26 | 0.11 | 0.51 | 0.76 | 1.88 | 1.83 | 1.62 | 2.22 | 3.35 | 8.0        |

For  $\lambda > 7\mu$ , becomes opaque, metallic reflection at  $8.50\mu$ ,  $9.02$ ,  $20.75$ – $24.4\mu$ , then transparent again.

The above are taken from Kayser's "Handbuch der Spectroscopie," vol. iii.

## TRANSMISSIBILITY OF RADIATION.

TABLE 217. — Color Screens.

The following light-filters are quoted from Landolt's "Das optische Drehungsvermögen, etc." 1898. Although only the potassium salt does not keep well it is perhaps safer to use freshly prepared solutions.

| Color.             | Thick-<br>ness.<br>mm. | Water solutions of                       | Grammes of<br>substance<br>in 100 c.cm. | Optical cen-<br>tre of band,<br>$\mu$ | Transmission.   |
|--------------------|------------------------|--|---|---------------------------------------|---|
| Red                | 20                     | Crystal-violet, 5B0                      | 0.005                                   | 0.6659                                | } begins about 0.718 $\mu$ .<br>} ends sharp at 0.639 $\mu$ . |

TABLE 218. — Color Screens.

The following list is condensed from Wood's Physical Optics :

Methyl violet, 4R (Berlin Anilin Fabrik) very dilute, and nitroso-dimethyl-aniline transmits 0.365 $\mu$ .

Methyl violet + chinin-sulphate (separate solutions), the violet solution made strong enough to blot out 0.4359 $\mu$ , transmits 0.4047 and 0.4048, also faintly 0.3984.

Cobalt glass + aesculin solution transmits 0.4359 $\mu$ .

Guinea green B extra (Berlin) + chinin sulphate transmits 0.4916 $\mu$ .

Neptune green (Bayer, Elberfeld) + chrysoidine. Dilute the latter enough to just transmit 0.5790 and 0.5461; then add the Neptune green until the yellow lines disappear.

Chrysoidine + eosine transmits 0.5790 $\mu$ . The former should be dilute and the eosine added until the green line disappears.

Silver chemically deposited on a quartz plate is practically opaque except to the ultra-violet region 0.3160-0.3260 where 90% of the energy passes through. The film should be of such thickness that a window backed by a brilliantly lighted sky is barely visible.

In the following those marked with a \* are transparent to a more or less degree to the ultra-violet :

\* Cobalt chloride: solution in water, — absorbs 0.50-0.53 $\mu$ ; addition of CaCl<sub>2</sub> widens the band to 0.47-0.50. It is exceedingly transparent to the ultra-violet down to 0.20. If dissolved in methyl alcohol + water, absorbs 0.50-0.53 and everything below 0.35. In methyl alcohol alone 0.485-0.555 and below 0.40 $\mu$ .

Copper chloride: in ethyl alcohol absorbs above 0.585 and below 0.535; in alcohol + 50% water, above 0.595 and below 0.37 $\mu$ .

Neodymium salts are useful combined with other media, sharpening the edges of the absorption bands. In solution with bichromate of potash, transmits 0.535-0.565 and above 0.60 $\mu$ , the bands very sharp (a useful screen for photographing with a visually corrected objective).

Praesodymium salts: three strong bands at 0.482, .468, .444. In strong solutions they fuse into a sharp band at 0.435-0.485 $\mu$ . Absorption below 0.34.

Picric acid absorbs 0.36-0.42 $\mu$ , depending on the concentration.

Potassium chromate absorbs 0.40-0.35, 0.30-0.24, transmits 0.23 $\mu$ .

\* Potassium permanganate: absorbs 0.555-0.50, transmits all the ultra-violet.

Chromium chloride: absorbs above 0.57, between 0.50 and .39, and below 0.33 $\mu$ . These limits vary with the concentration.

Aesculin: absorbs below 0.363 $\mu$ , very useful for removing the ultra-violet.

\* Nitroso-dimethyl-aniline: very dilute aqueous solution absorbs 0.49-0.37 and transmits all the ultra-violet.

Very dense cobalt glass + dense ruby glass or a strong potassium bichromate solution cuts off everything below 0.70 and transmits freely the red.

Iodine: saturated solution in CS<sub>2</sub> is opaque to the visible and transparent to the infra-red.

## TRANSMISSIBILITY OF RADIATION.

TABLE 219. — Color Screens. Jena Glasses.

|    | Kind of Glass.         | Maker's No.        | Color.                             | Region Transmitted.                                       | Thickness, mm. |

| "  | " . . . . .            | "                  | " . . . . .                        | { Blue, violet, blue-green (weakened), no red }           | 2-5            |
| 12 | Cobalt . . . . .       | 424 <sup>III</sup> | Blue . . . . .                     | Blue, violet, extreme red . . . . .                       | 4-5            |
| 13 | Nickel . . . . .       | 450 <sup>III</sup> | Dark violet . . . . .              | Violet (G-H), extreme red . . . . .                       | 6.             |
| 14 | Violet . . . . .       | 452 <sup>III</sup> | " . . . . .                        | Violet (G-H), some weakened . . . . .                     | 7.             |
| 15 | Gray . . . . .         | 444 <sup>III</sup> | { Gray, no recognizable color }    | All parts of the spectrum weakened                        | 0.1-8          |
| 16 | " . . . . .            | 445 <sup>III</sup> |                                    |   |                |

See "Über Farbläser für wissenschaftliche und technische Zwecke," by Zsigmondy, Z. für Instrumentenkunde, 21, 1901 (from which the above table is taken), and "Über Jenenser Lichtfilter," by Grebe, same volume.

(The following notes are quoted from Everett's translation of the above in the English edition of Hovestadt's "Jena Glass.")

Division of the spectrum into complementary colors:

1st by 2728 (deep red) and 2742 (blue, like copper sulphate).

2nd by 454<sup>III</sup> (bright yellow) and 447<sup>III</sup> (blue, like cobalt glass).

3rd by 433<sup>III</sup> (greenish-yellow) and 424<sup>III</sup> (blue).

Thicknesses necessary in above: 2728, 1.6-1.7 mm.; 2742, 5; 454<sup>III</sup>, 16; 447<sup>III</sup>, 1.5-2.0; 433<sup>III</sup>, 2.5-3.5; 424<sup>III</sup>, 3 mm.

Three-fold division into red, green and blue (with violet):

2728, 1.7 mm.; 414<sup>III</sup>, 10 mm.; 447<sup>III</sup>, 1.5 mm., or by

2728, 1.7 mm.; 436<sup>III</sup>, 2.6 mm.; 447<sup>III</sup>, 1.8 mm.

Grebe found the three following glasses specially suited for the additive methods of three-color projection:

2745, red; 438<sup>III</sup>, green; 447<sup>III</sup>, blue violet;

corresponding closely to Young's three elementary color sensations.

Most of the Jena glasses can be supplied to order, but the absorption bands vary somewhat in different meltings.

See also "Atlas of Absorption Spectra," Uhler and Wood, Carnegie Institution Publications, 1907.

TABLE 219a. — Water Vapor.

Values of  $a$  in  $I = I_0 e^{-ad}$ ,  $d$  in c. m.  $I_0$ ;  $I$ , intensity before and after transmission.

TABLE 220. — Tartaric Acid; Camphor; Santonin; Santonio Acid; Cane Sugar.

A few examples are here given showing the effect of wave-length on the rotation of the plane of polarization. The rotations are for a thickness of one decimeter of the solution. The examples are quoted from Landolt & Börnstein's "Phys. Chem. Tab." The following symbols are used:—

$\rho$  = number grams of the active substance in 100 grams of the solution.  
 $c$  = " " solvent " " " "  
 $q$  = " " active " " cubic centimeter "

Right-handed rotation is marked +, left-handed —.

| Line of spectrum. | Wave-length according to Angström in cms. $\times 10^6$ . | Tartaric acid,* $C_4H_6O_6$ , dissolved in water.<br>$q = 50$ to $95$ , temp. = $24^\circ$ C. | Camphor,* $C_{10}H_{16}O$ , dissolved in alcohol.<br>$q = 50$ to $95$ , temp. = $22.9^\circ$ C. | Santonin,† $C_{15}H_{18}O_3$ , dissolved in chloroform.<br>$q = 75$ to $96.5$ , temp. = $20^\circ$ C. |  |  |

\* The paper is quoted from a paper by Ketteler in "Wied. Ann." vol. 21, p. 444. The wave-lengths are for the Fraunhofer lines, Angström's values for the ultra violet sun, and Cornu's values for the cadmium lines.

TABLE 222.  
NEWTON'S RINGS.

Newton's Table of Colors.

The following table gives the thickness in millionths of an inch, according to Newton, of a plate of air, water, and glass corresponding to the different colors in successive rings commonly called colors of the first, second, third, etc., orders.

| Order.      | Color for reflected light. | Color for transmitted light. | Thickness in millionths of an inch for — |        |        | Order.    | Color for reflected light. | Color for transmitted light. | Thickness in millionths of an inch for — |                   |             |           |      |      |
|-------------|----------------------------|------------------------------|--|--------|--------|-----------|----------------------------|------------------------------|--|-------------------|-------------|-----------|------|------|
|             |                            |                              | Air.                                     | Water. | Glass. |           |                            |                              | Air.                                     | Water.            | Glass.      |           |      |      |

The above table has been several times revised both as to the colors and the numerical values. Professors Reinold and Rucker, in their investigations on the measurement of the thickness of soap films, found it necessary to make new determinations. They give a shorter series of colors, as they found difficulty in distinguishing slight differences of shade, but divide each color into ten parts and tabulate the variation of thickness in terms of the tenth of a color band. The position in the band at which the thickness is given and the order of color are indicated by numerical subscripts. For example: R<sub>1.5</sub> indicates the red of the first order and the fifth tenth from the edge furthest from the red edge of the spectrum. The thicknesses are in millionths of a centimeter.

\* The colors marked are the same as the corresponding colors in Newton's table.

CONDUCTIVITY FOR HEAT.

The coefficient  $k$  is the quantity of heat in small calories which is transmitted per second through a plate one centimeter thick per square centimeter of its surface when the difference of temperature between the two faces of the plate is one degree Centigrade. The coefficient  $k$  is found to vary with the absolute temperature of the plate, and is expressed approximately by the equation  $k_t = k_0 [1 + a(t - t_0)]$ .  $k_0$  is the resistance at  $t_0$ , the lower temperature of the bracketed pairs in the table,  $k_t$  that at temperature  $t$  and  $a$  is a constant.

## DIFFUSIVITIES.

The diffusivity of a substance  $= h^2 = k/c\rho$ , where  $k$  is the conductivity for heat,  $c$  the specific heat and  $\rho$  the density. (Kelvin.) The values are mostly for room temperatures, about 18°C.

Taken from "An Introduction to the Mathematical Theory of Heat Conduction," Ingersoll and Zobel, 1913.

## HEAT OF COMBUSTION.

Heat of combustion of some common organic compounds.  
 Products of combustion, CO<sub>2</sub> or SO<sub>2</sub> and water, which is assumed to be in a state of vapor.

\* Combustion at constant pressure.

## COMBINATION.

caused to combine with oxygen or the negative radical, the numbers indicate the amount of water, in the same form from 0° to 1° C. by the addition of that heat.

† Total heat from elements.

## LATENT HEAT OF VAPORIZATION.

The temperature of vaporization in degrees Centigrade is indicated by  $T$ ; the latent heat in large calories per kilogram or in small calories or therms per gram by  $H$ ; the total heat from  $0^{\circ}$  C, in the same units by  $H'$ . The pressure is that due to the vapor at the temperature  $T$ .

## LATENT HEAT OF FUSION.

This table contains the latent heat of fusion of a number of solid substances in large calories per kilogram or small calories or therms per gram. It has been compiled principally from Landolt and Börnstein's tables. *C* indicates the composition, *T* the temperature Centigrade, and *H* the latent heat.

\* Total heat from 0° C.

† U. S. Bureau of Standards, 1913, in terms of 15° calorific.

‡ 1903, based on electrical measurements, assuming mechanical equivalent = 4.187, and in terms of the value of the international volt in use after 1911.

SMITHSONIAN TABLES.

## MELTING-POINTS OF THE CHEMICAL ELEMENTS.

The metals in heavier type are often used as standards.

The melting-points are reduced as far as possible to a common temperature scale which is the one used by the United States Bureau of Standards in certifying pyrometers. This scale is defined in terms of Wien's law with  $C_2$  taken as 1,4500, and on which the melting-point of platinum is 1755° C (Nernst and Wartenburg, 1751; Waidner and Burgess, 1753; Holborn and Valentiner, 1770; see C. R. 148, p. 1177, 1909). Above 1100° C, the temperatures are expressed to the nearest 5° C. Temperatures above the platinum point may be uncertain by over 50° C.

| Element.        | Melting-point.           | Remarks.                                 | Element.         | Melting-point. | Remarks.                                     |
|-----------------|--------------------------|--|------------------|----------------|--|
| <b>Aluminum</b> | 658 ± 1                  | Most samples give 657 or less (Burgess). | Manganese        | 1260           | Burgess-Waltenberg                           |
| <b>Antimony</b> | 630 ± 1                  | "Kahlbaum" purity.                       | Mercury          | - 38.7         |  |

The accuracy of the melting-points is 5 to 10 units. Geophysical Laboratory. See also Day and Sosman, Am. J. of Sc. xxxi, p. 341, 1911.

## LOWERING OF FREEZING-POINTS BY SALTS IN SOLUTION.

In the first column is given the number of gram-molecules (anhydrous) dissolved in 1000 grams of water; the second contains the molecular lowering of the freezing-point; the freezing-point is therefore the product of these two columns. After the chemical formula is given the molecular weight, then a reference number.

| $\frac{\text{g. mol.}}{1000 \text{ g. H}_2\text{O}}$ | Molecular Lowering.  | $\frac{\text{g. mol.}}{1000 \text{ g. H}_2\text{O}}$         | Molecular Lowering.                  | $\frac{\text{g. mol.}}{1000 \text{ g. H}_2\text{O}}$ | Molecular Lowering.               | $\frac{\text{g. mol.}}{1000 \text{ g. H}_2\text{O}}$ | Molecular Lowering. |

## RISE OF BOILING-POINT PRODUCED BY SALTS DISSOLVED IN WATER.\*

This table gives the number of grams of the salt which, when dissolved in 100 grams of water, will raise the boiling-point by the amount stated in the headings of the different columns. The pressure is supposed to be 76 centimeters.

| Salt.  | 1° C. | 2°   | 3°    | 4°    | 5°                            | 7°    | 10°                         | 15°    | 20°               | 25°     |
|--|-------|------|-------|-------|-------------------------------|-------|-----------------------------|--------|-------------------|---------|
| BaCl <sub>2</sub> + 2H <sub>2</sub> O . . .  | 15.0  | 31.1 | 47.3  | 63.5  | (71.6 gives 4° rise of temp.) |       |                             |        |                   |         |

## FREEZING MIXTURES.\*

Column 1 gives the name of the principal refrigerating substance, *A* the proportion of that substance, *B* the proportion of a second substance named in the column, *C* the proportion of a third substance, *D* the temperature of the substances before mixture, *E* the temperature of the mixture, *F* the lowering of temperature, *G* the temperature when all snow is melted, when snow is used, and *H* the amount of heat absorbed in heat units (small calories when *A* is grams). Temperatures are in Centigrade degrees.

| Substance.  | <i>A</i>              | <i>B</i>              | <i>C</i>                            | <i>D</i> | <i>E</i> | <i>F</i> | <i>G</i> | <i>H</i> |

## LINEAR EXPANSION OF THE ELEMENTS.

In the heading of the columns  $t$  is the temperature or range of temperature;  $C$  is the coefficient of linear expansion;  $A_1$  is the authority for  $C$ ;  $M$  is the mean coefficient of expansion between  $0^\circ$  and  $100^\circ$  C.;  $\alpha$  and  $\beta$  are the coefficients in the equation  $l_t = l_0(1 + \alpha t + \beta t^2)$ , where  $l_0$  is the length at  $0^\circ$  C. and  $l_t$  the length at  $t^\circ$  C.;  $A_2$  is the authority for  $\alpha$ ,  $\beta$ , and  $M$ .

| Substance.                        | $t$         | $C \times 10^4$ | $A_1$ | $M \times 10^4$ | $\alpha \times 10^4$ | $\beta \times 10^6$ | $A_2$ |

13 Day and Sos-

man.

The above table has been partly compiled from the results published by Fizeau, "Comptes Rendus," vol. 68, and Matthiessen, "Proc. Roy. Soc.," vol. 15.

The Holborn-Day and Day and Sosman data are for temperatures from  $20^\circ$  to  $1000^\circ$  C. The Dittenberger,  $0^\circ$  to  $600^\circ$  C.

LINEAR EXPANSION OF MISCELLANEOUS SUBSTANCES.

The coefficient of cubical expansion may be taken as three times the linear coefficient.  $t$  is the temperature or range of temperature,  $C$  the coefficient of expansion, and  $A$  the authority.

| Substance.                              | $t$         | $C \times 10^4$ | $A$ . | Substance.                             | $t$         | $C \times 10^4$ | $A$ . |

## CUBICAL EXPANSION OF SOLIDS.

If  $v_2$  and  $v_1$  are the volumes at  $t_2$  and  $t_1$  respectively, then  $v_2 = v_1 (1 + C\Delta t)$ ,  $C$  being the coefficient of cubical expansion and  $\Delta t$  the temperature interval. Where only a single temperature is stated  $C$  represents the true coefficient of cubical expansion at that temperature.\*

| Substance.                               | $t$ or $\Delta t$ | $C \times 10^4$ | Authority.          |

SMITHSONIAN TABLES.

## CUBICAL EXPANSION OF LIQUIDS.

If  $V_0$  is the volume at  $0^\circ$  then at  $t^\circ$  the expansion formula is  $V_t = V_0 (1 + \alpha t + \beta t^2 + \gamma t^3)$ . The table gives values of  $\alpha$ ,  $\beta$  and  $\gamma$  and of  $C$ , the true coefficient of cubical expansion, at  $20^\circ$  for some liquids and solutions.  $\Delta t$  is the temperature range of the observation and  $A$  the authority.

| Liquid.                    | $\Delta t$ | $\alpha \ 10^3$ | $\beta \ 10^6$ | $\gamma \ 10^9$ | $C \ 10^3$<br>at $20^\circ$ | $A$ |

COEFFICIENTS OF THERMAL EXPANSION.

Coefficients of Expansion of Gases.

Pressures are given in centimeters of mercury.

| Coefficient at Constant Volume.           |              |                    |            | Coefficient at Constant Pressure.               |              |                    |            |

\* Admitting an error of 1 part per 1000 in the electrical scale.

The mean of the last four then gives

**1 small (20° C) calory = 4.181 × 10<sup>7</sup> ergs.**

1 small (15° C) calory = 4.185 × 10<sup>7</sup> ergs assuming sp. ht. of water at 20° = 0.9990.

TABLE 261. — Mean Specific Heats of Quartz, Silica Glass, and Platinum from zero, C., to the temperature named.

The mean specific heats of quartz above 550° are here increased by the heat (2.3 calories) of the inversion at 575°. The accuracy is probably better than 2 per mille.

| Interval. | Quartz. | Silica Glass. | Platinum. | Obs.—calculated for Pt. |
|-----------|---------|---------------|-----------|-------------------------|
| 0-100°    | .1870   | .1845         | —         | —                       |
| 0-300°    | .2169   | .2124         | .03283    | .00000                  |
| 0-500°    | .2382   | .2303         | .03363    | + .00012                |
| 0-550°    | .2441   | —             | —         | —                       |
| 0-600°    | .2520   | —             | —         | —                       |
| 0-700°    | .2555   | .2433         | .03424    | + .00005                |
| 0-900°    | .2608   | .2523         | .03487    | .00000                  |
| 0-1100°   | .2654   | —             | .03551    | — .00004                |
| 0-1300°   | —       | —             | .03620    | — .00003                |

The results for Platinum follow the formula :

Sp. Heat = .03174 + .000 0034  $\theta$  very closely. If the formula were strictly correct the *true specific heat* at any temp. would be : .03174 + .000 006 8  $\theta$ , which is probably true to 1% as it is.

Determinations by W. P. White. Geographical Laboratory.

## THERMOMETERS.

TABLE 266. — Gas and Mercury Thermometers.

If  $t_H$ ,  $t_N$ ,  $t_{CO_2}$ ,  $t_{16}$ ,  $t_{59}$ ,  $t_T$  are temperatures measured with the hydrogen, nitrogen, carbonic acid,  $16^{III}$ ,  $59^{III}$ , and "verre dur" (Tonnelot), respectively, then

$$t_H - t_T = \frac{(100 - t)t}{100^2} [-0.61859 + 0.0047351.t - 0.000011577.t^2]^*$$

$$t_N - t_T = \frac{(100 - t)t}{100^2} [-0.55541 + 0.0048240.t - 0.000024807.t^2]^*$$

TABLE 275. — Platinum Resistance Thermometers.

Callendar has shown that if we define the platinum temperature,  $pt$ , by  $pt = 100 \{ (R - R_0) / (R_{100} - R_0) \}$ , where  $R$  is the observed resistance at  $t^\circ \text{C.}$ ,  $R_0$  that at  $0^\circ$ ,  $R_{100}$  at  $100^\circ$ , then the relation between the platinum temperature and the temperature  $t$  on the scale of the gas thermometer is represented by  $t - pt = \delta \{ t / 100 - 1 \} t / 100$  where  $\delta$  is a constant for any given sample of platinum and about 1.50 for pure platinum (impure platinum having higher values). This holds good between  $-23^\circ$  and  $450^\circ$  when  $\delta$  has been determined by the boiling point of sulphur ( $445^\circ$ ).

See Waidner and Burgess, Bul. Bureau Standards, 6, p. 149, 1909.

TABLE 276. — Thermodynamic Temperature of the Ice Point, and Reduction to Thermodynamic Scale.

Mean =  $273.10^\circ \text{C.}$  (ice point)

For a discussion of the various values and for the corrections of the various gas thermometers to the thermodynamic scale see Buckingham, Bull. Bureau Standards, 3, p. 237, 1907.

Scale Corrections for Gas Thermometers.

\* Thermoelectric extrapolation. † Optical extrapolation.

(Day and Sosman, Journal de Physique, 1912. Mesure des températures élevées.) A few additional points are: H, boils  $-252.7^\circ$ ; O, boils  $-182.9^\circ$ ; Hg. freezes  $-37.7^\circ$ ; Alumina melts  $2000^\circ$ ; Tungsten melts  $3000^\circ$ .

### CORRECTION FOR TEMPERATURE OF MERCURY IN THERMOMETER STEM.

The Stem Correction is proportional to  $n\beta(T-t)$ : where  $n$  is the number of degrees in the exposed stem;  $\beta$  is the apparent coefficient of expansion of mercury in the glass;  $T$  is the measured temperature; and  $t$  is the mean temperature of the exposed stem determined by another thermometer, exposed some 10 cm. from, and at about half the height of, the exposed stem of the first.

For temperatures up to  $100^{\circ}\text{C}$ , the value of  $\beta$  is for:

Jena glass XVI<sup>III</sup> or Greiner and Friedrich resistance glass,  $\frac{1}{6300}$  or 0.000159;

Jena glass 59<sup>III</sup>,  $\frac{1}{6100}$  or 0.000164.

At  $100^{\circ}$  the correction is in round numbers  $0.01^{\circ}$  for each degree of the exposed stem; at  $200^{\circ}$   $0.02^{\circ}$ ; and for higher temperatures proportionately greater. At  $500^{\circ}$  it may amount to  $0.07^{\circ}$  for each exposed degree.

Tables 278-280 are taken from Rimbach, *Zeitschrift für Instrumentenkunde*, 10, 153, 1890, and apply to thermometers of Jena or of resistance glass.

**TABLE 278. — Stem Correction for Thermometer of Jena Glass ( $0^{\circ}$ - $360^{\circ}\text{C}$ ).**

Degree length 0.9 to 1.1 mm;  $t$  = the observed temperature;  $t'$  = that of the surrounding air 1 dm. away;  $n$  = the length of the exposed thread.

TABLE 282. — Standard Calibration Curve for Copper — Constantan Thermo-Element.

For use in conjunction with a deviation curve determined by the calibration of the particular element at some of the following fixed points:

Water, boiling-point, 100°, 4276 microvolts; Naphthalene, boiling-point, 217.95, 10248 mv.; Tin, melting-point, 231.9, 11009 mv.; Benzophenone, boiling-point, 305.9, 15203 mv.; Cadmium, melting-point, 320.9, 16083 mv.

RADIATION CONSTANTS.

TABLE 283.—Radiation Formulæ and Constants for Perfect Radiator.

The radiation per sq. cm. from a "black body" (exclusive of convection losses) at the temperature  $T^{\circ}$  (absolute, C) to one at  $t^{\circ}$  is equal to

$$J = \sigma (T^4 - t^4) \quad (\text{Stefan-Boltzmann});$$

where  $\sigma = 1.374 \times 10^{-12}$  gram-calories per second per sq. centimeter.

$= 8.26 \times 10^{-11}$  " " " minute " " "

$= 5.75 \times 10^{-12}$  watts per sq. centimeter.

The distribution of this energy in the spectrum is represented by Planck's formula:

$$J_{\lambda} = C_1 \lambda^{-5} [e^{\frac{C_2}{\lambda T}} - 1]^{-1}$$

where  $J_{\lambda}$  is the intensity of the energy at the wave-length  $\lambda$  ( $\lambda$  expressed in microns,  $\mu$ ) and  $e$  is the base of the Napierian logarithms.

$$C_1 = 9.226 \times 10^{-23} \text{ for } J \text{ in } \frac{\text{gram. cal.}}{\text{sec. cm.}^2} = 3.86 \times 10^{-22} \text{ for } J \text{ in } \frac{\text{watts}}{\text{cm.}^2}$$

$$C_2 = 1.4450 \text{ for } \lambda \text{ in cm.}$$

$$J_{\text{max}} = 3.11 \times 10^{+4} T^5 \text{ for } J \text{ in } \frac{\text{gram. cal.}}{\text{sec. cm.}^2} = 1.30 \times 10^{+5} T^5 \text{ for } J \text{ in } \frac{\text{watts}}{\text{cm.}^2}$$

$$\lambda_{\text{max}} T = 0.2910 \text{ for } \lambda \text{ in cm.}$$

$h = \text{Planck's unit} = \text{elementary "Wirkungs quantum"} = 6.83 \times 10^{-27} \text{ ergs. sec.}$

$k = \text{constant of entropy equation} = 1.42 \times 10^{-16} \text{ ergs./degrees.}$

TABLE 284.—Radiation in Gram-Calories per 24 Hours per sq. cm. from a Perfect Radiator at  $t^{\circ}$  C to an absolutely Cold Space ( $-273^{\circ}$  C).

Computed from the Stefan-Boltzmann formula.

## COOLING BY RADIATION AND CONVECTION.

TABLE 286. — At Ordinary Pressures.

According to McFarlane \* the rate of loss of heat by a sphere placed in the centre of a spherical enclosure which has a blackened surface, and is kept at a constant temperature of about 14° C, can be expressed by the equations

$$e = .000238 + 3.06 \times 10^{-6}t - 2.6 \times 10^{-8}t^2,$$

when the surface of the sphere is blackened, or

$$e = .000168 + 1.98 \times 10^{-6}t - 1.7 \times 10^{-8}t^2,$$

when the surface is that of polished copper. In these equations,  $e$  is the amount of heat lost in c. g. s. units, that is, the quantity of heat, small calories, radiated per second per square centimeter of surface of the sphere, per degree difference of temperature  $t$ , and  $t$  is the difference of temperature between the sphere and the enclosure. The medium through which the heat passed was moist air. The following table gives the results.

| Difference of temperature $t$ | Value of $e$ .    |                    | Ratio. |
|-------------------------------|-------------------|--------------------|--------|
|                               | Polished surface. | Blackened surface. |        |

COOLING BY RADIATION AND CONVECTION.

TABLE 288. — Cooling of Platinum Wire in Copper Envelope.

Bottomley gives for the radiation of a bright platinum wire to a copper envelope when the space between is at the highest vacuum attainable the following numbers: —

$$t = 408^{\circ} \text{C.}, et = 378.8 \times 10^{-4}, \text{ temperature of enclosure } 16^{\circ} \text{C.}$$

$$t = 505^{\circ} \text{C.}, et = 726.1 \times 10^{-4}, \text{ " " " } 17^{\circ} \text{C.}$$

It was found at this degree of exhaustion that considerable relative change of the vacuum produced very small change of the radiating power. The curve of relation between degree of vacuum and radiation becomes asymptotic for high exhaustions. The following table illustrates the variation of radiation with pressure of air in enclosure.

| Temp. of enclosure 16° C., t = 408° C. |                           | Temp. of enclosure 17° C., t = 505° C. |                           |

NOTE. — An interesting example (because of its practical importance in electric lighting) of the effect of difference of surface condition on the radiation of heat is given on the authority of Mr. Evans and himself in Bottomley's paper. The energy required to keep up a certain degree of incandescence in a lamp when the filament is dull black and when it is "flashed" with coating of hard bright carbon, was found to be as follows: —

Dull black filament, 57.9 watts.  
Bright " " 39.8 watts.

## PROPERTIES OF STEAM.

## Metric Measure.

The temperature Centigrade and the absolute temperature in degrees Centigrade, together with other data for steam or water vapor stated in the headings of the columns, are here given. The quantities of heat are in therms or calories according as the gram or the kilogram is taken as the unit of mass.

| Temp. C. | Absolute temp. | Pressure in mm. of mercury. | Pressure in grams per sq. centimeter = $p$ . | Pressure in atmospheres. | Total heat of evaporation from $0^{\circ}$ at $p = H$ . | Heat of liquid = $h$ . | Heat of evaporation = $H - h$ . | Outer latent or external-work heat = $A p$ . | Total heat of steam = $H - A p$ . | Inner latent or internal-work heat = $H - (h + A p)$ . | Liters per gram, or cubic meters per kilog. = $v$ . | Ratio of inner latent heat to volume of steam.† |

\* Where  $A$  is the reciprocal of the mechanical equivalent of the thermal unit.

†  $\frac{H - (h + A p)}{v} = \frac{\text{internal-work pressure}}{\text{mechanical equivalent of heat}}$  Where  $v$  is taken in litres the pressure is given per square decimetre, and where  $v$  is taken in cubic metres the pressure is given per square metre, — the mechanical equivalent being that of the therm and the kilogram-degree or calorie respectively.

TABLE 291.  
PROPERTIES OF STEAM.

British Measure.

The quantities given in the different columns of this table are sufficiently explained by the headings. The abbreviation B. T. U. stands for British thermal units. With the exception of column 3, which was calculated for this table, the data are taken from a table given by Dweishauvers-Dery (Trans. Am. Soc. Mech. Eng. vol. xi.).

| Pressure in pounds per square inch. | Pressure in pounds per square foot. | Pressure in atmospheres. | Temp. in degrees Fahr. | Volume per pound in cubic feet. | Weight per cubic foot in pounds. | Heat of water per pound in B. T. U. | Internal latent heat per pound of steam in B. T. U. | External latent heat of steam in B. T. U. | Total latent heat per pound of steam in B. T. U. | Total heat per pound of steam in B. T. U. |

## PROPERTIES OF STEAM.

British Measure.

|    | Pressure in pounds per square inch. | Pressure in pounds per square foot. | Pressure in atmospheres. | Temp. in degrees Fahr. | Volume per pound in cubic feet. | Weight per cubic foot in pounds. | Heat of water per pound in B. T. U. | Internal latent heat per pound of steam in B. T. U. | External latent heat per pound of steam in B. T. U. | Total latent heat per pound of steam in B. T. U. | Total heat per pound of steam in B. T. U. |

## PROPERTIES OF STEAM.

British Measure.

| Pressure in pounds per square inch. | Pressure in pounds per square foot. | Pressure in atmospheres. | Temp. in degrees Fahr. | Volume per pound in cubic feet. | Weight per cubic foot in pounds. | Heat of water per pound in B. T. U. | Internal latent heat per pound of steam in B. T. U. | External latent heat per pound of steam in B. T. U. | Total latent heat per pound of steam in B. T. U. | Total heat per pound of steam in B. T. U. |

TABLE 291 (continued).  
 PROPERTIES OF STEAM.

British Measure.

|            | Pressure in pounds per square inch. | Pressure in pounds per square foot. | Pressure in atmospheres. | Temp. in degrees Fahr. | Volume per pound in cubic feet. | Weight per cubic foot in pounds. | Heat of water per pound in B. T. U. | Internal latent heat per pound of steam in B. T. U. | External latent heat per pound of steam in B. T. U. | Total latent heat per pound of steam in B. T. U. | Total heat per pound of steam in B. T. U. |

## PROPERTIES OF STEAM.

British Measure.

|            | Pressure in pounds per square inch. | Pressure in pounds per square foot. | Pressure in atmospheres. | Temp. in degrees Fahr. | Volume per pound in cubic feet. | Weight per cubic foot in pounds. | Heat of water per pound in B. T. U. | Internal latent heat per pound of steam in B. T. U. | External latent heat per pound of steam in B. T. U. | Total latent heat per pound of steam in B. T. U. | Total heat per pound of steam in B. T. U. |

The last of the above determinations is the result of an extended series of measurements upon various forms of condensers, and is believed to be correct within 1/100 per cent. This, however, assumes that the International Ohm is  $10^9$  c.g.s. units. The value of  $V$  is therefore subject to one-half the error of the International Ohm.

**SMITHSONIAN TABLES.**

## ABSOLUTE MEASUREMENTS OF CURRENTS AND OF THE ELECTRO-MOTIVE FORCE OF STANDARD CELLS.

\* The values given in these columns are not strictly absolute volts since they were in most cases determined in terms of an absolute ampere and an international ohm. Hence they may be called "semi-absolute." No absolute determinations of the ohm have been made in recent times, but some are in progress.

† Other values usually given as Kahle's results and officially used by the Reichsanstalt are voltmeter determinations. To include them here would necessitate including many others similarly made. The value 1.1183 includes 5 filter paper determinations out of 26 observations.

‡ These values have been corrected for the difference between the French ohm at this time and that in use elsewhere. (C. R. vol. 153, p. 718.)

Measurements prior to Van Dijk (1906) and the subsequent filter paper voltmeter determinations are now only of historical interest, but the large amount of work done in recent years makes these early determinations of especial interest. The errors due to the use of filter paper and other impurities (acid, alkali, colloidal matter, etc.) in the voltmeter electrolyte make it impossible to apply corrections. The values for the cell are not readily comparable owing to variations in the voltage of the cell itself and the unit of resistance. See Dorn, Wiss. Abhl. der Phys. Tech. Reich., vol. 11, p. 257. Since 1911 the voltage adopted for the Weston Normal Cell at 20° C. is 1.0183 international volts in all the leading countries. The international volt is to be distinguished from the absolute volt since it is based on the definition of the mercury ohm and the silver voltmeter, taking the electrochemical equivalent of silver to be 1.11800 mg per coulomb. The difference between the international volt and the absolute volt is negligible for practical purposes. The temperature coefficient of the Weston Normal Cell (saturated type) is given in Table 294. The new value of the Weston cell was adopted in the United States on January 1, 1911.

## COMPOSITION AND ELECTROMOTIVE FORCE OF VOLTAIC CELLS.

The electromotive forces given in this table approximately represent what may be expected from a cell in good working order, but with the exception of the standard cells all of them are subject to considerable variation.

\* E. M. F. hitherto used at Bureau of Standards. See p. 251. The temperature formula is  $E_t = E_{20} - 0.0000406(t-20) - 0.00000095(t-20)^2 + 0.0000001(t-20)^3$ . † The value given is that adopted by the Chicago International Electrical Congress in 1893. The temperature formula is  $E_t = E_{15} - 0.00119(t-15) - 0.00007(t-15)^2$ .

† F. Streintz gives the following value of the temperature variation  $\frac{dE}{dt}$  at different stages of charge :

|                             |        |        |        |        |        |        |        |
|-----------------------------|--------|--------|--------|--------|--------|--------|--------|

Ayrton and Perry's results, prepared by Ayrton.

## CONTACT DIFFERENCE OF POTENTIAL IN VOLTS.

## Solids with Solids in Air.\*

The following results are the "Volta differences of potential," as measured by an electrometer. They represent the difference of the potentials of the air near each of two metals placed in contact. This should not be confused with the junction electromotive force at the junction of two metals in metallic contact, which has a definite value, proportional to the coefficient of Peltier effect. The Volta difference of potential has been found to vary with the condition of the metallic surfaces and with the nature of the surrounding gas. No great reliance, therefore, can be placed on the tabulated values.

The temperature of the substances during the experiment was about 18° C.

The numbers not marked were obtained by direct experiment, those marked with a dagger by calculation, on the assumption that in a compound circuit of metals, all at the same temperature, there is no electromotive force.

The numbers in the same vertical column are the differences of potential in volts between the substance named at the top of the column and the substance named on the same line in the first column, when the two substances are in contact.

The metals used were those ordinarily obtained in commerce.

\* Everett's "Units and Physical Constants." The table is from Ayrton and Perry's experiments, and was prepared by Ayrton.

## DIFFERENCE OF POTENTIAL BETWEEN METALS IN SOLUTIONS OF SALTS.

The following numbers are given by G. Magnanini\* for the difference of potential in hundredths of a volt between zinc in a normal solution of sulphuric acid and the metals named at the head of the different columns when placed in the solution named in the first column. The solutions were contained in a U-tube, and the sign of the difference of potential is such that the current will flow from the more positive to the less positive through the external circuit.

|| A quantity of bromine was used corresponding to NaOH = 1.

## THERMOELECTRIC POWER.

The thermoelectric power of a circuit of two metals is the electromotive force produced by one degree C. difference of temperature between the junctions. The thermoelectric power varies with the temperature, thus: thermoelectric power =  $Q = dE/dt = A + Bt$ , where  $A$  is the thermoelectric power at  $0^\circ\text{C}$ .,  $B$  is a constant, and  $t$  is the mean temperature of the junctions. The neutral point is the temperature at which  $dE/dt = 0$ , and its value is  $-A/B$ . When a current is caused to flow in a circuit of two metals originally at a uniform temperature, heat is liberated at one of the junctions and absorbed at the other. The rate of production or liberation of heat at each junction, or Peltier effect, is given in calories per second, by multiplying the current by the coefficient of the Peltier effect. This coefficient in calories per coulomb =  $QT/\mathcal{J}$ , in which  $Q$  is in volts,  $T$  is the absolute temperature of the junction, and  $\mathcal{J} = 4.19$ . Heat is also liberated or absorbed in each of the metals as the current flows through portions of varying temperature. The rate of production or liberation of heat in each metal, or the Thomson effect, is given in calories per second by multiplying the current by the coefficient of the Thomson effect. This coefficient, in calories per coulomb, =  $BT\theta/\mathcal{J}$ , in which  $B$  is in volts per degree C.,  $T$  is the mean absolute temperature of the junctions, and  $\theta$  is the difference of temperature of the junctions. ( $BT$ ) is Sir W. Thomson's "Specific Heat of electricity." The algebraic signs are so chosen in the following table that when  $A$  is positive, the current flows in the metal considered from the cold junction to the hot. When  $B$  is positive,  $Q$  increases (algebraically) with the temperature. The values of  $A$ ,  $B$ , and thermoelectric power, in the following table are with respect to lead as the other metal of the thermoelectric circuit. The thermoelectric power of a couple composed of two metals, 1 and 2, is given by subtracting the value for 2 from that for 1; when this difference is positive, the current flows from the cold junction to the hot in 1. In the following table,  $A$  is given in microvolts,  $B$  in microvolts per degree C., and the neutral point in degrees C.

The table has been compiled from the results of Becquerel, Matthiessen and Tait; in reducing the results, the electromotive force of the Grove and Daniell cells has been taken as 1.95 and 1.07 volts. The value for constantin was reduced from results given in Landolt-Börnstein's tables. The thermoelectric powers of antimony and bismuth alloys are given by Becquerel in the reference given below.

TABLE 299. — Thermoelectric Power of Alloys.

The thermoelectric powers of a number of alloys are given in this table, the authority being Ed. Becquerel. They are relative to lead, and for a mean temperature of 50° C. In reducing the results from copper as a reference metal, the thermoelectric power of lead to copper was taken as -1.9.

| Substance. | Relative quantity. | Thermoelectric power in microvolts. | Substance. | Relative quantity. | Thermoelectric power in microvolts. | Substance. | Relative quantity. | Thermoelectric power in microvolts. |
|------------|--------------------|-------------------------------------|------------|--------------------|-------------------------------------|------------|--------------------|-------------------------------------|

TABLE 300.—Thermoelectric Power against Platinum.

One junction is supposed to be at 0° C; + indicates that the current flows from the 0° junction into the platinum. The rhodium and iridium were rolled, the other metals drawn.\*

TABLE 302. — Peltier Effect.

The coefficient of Peltier effect may be calculated from the constants *A* and *B* of Table 298, as there shown. Experimental results, expressed in slightly different units, are here given. The figures are for the heat production at a junction of copper and the metal named, in calories per ampere-hour. The current flowing from copper to the metal named, a positive sign indicates a warming of the junction. The temperature not being stated by either author, and Le Roux not giving the algebraic signs, these results are not of great value.

| Calories per ampere-hour. |       |                 |           |       |       |                |       |      |      |       |       |

The legal value of the ohm is the resistance of a column of mercury of uniform cross-section, weighing 14.4521 gms., and having a length of 106.30 cms. This is known as the international ohm. Mercury ohms conforming to these specifications have been prepared in recent years at the Physikalisch-Technische Reichsanstalt, the National Physical Laboratory, and the Bureau of Standards. The wire standards of resistance at the above-named laboratories agree in value to within two parts in 100000. Hence there is a very close agreement in the values of precision resistances calibrated at these laboratories.

SMITHSONIAN TABLES.

## SPECIFIC RESISTANCE OF METALLIC WIRES.

This table is modified from the table compiled by Jenkin (1862) from Matthiessen's results by taking the resistance of silver, gold, and copper from the observed metre grammme value and assuming the densities found by Matthiessen, namely, 10.468, 19.265, and 8.95.

| Substance.   | Resistance at 0° C. of a wire one cm. long, one sq. cm. in section. | Resistance at 0° C. of a wire one metre long, one mm. in diam. | Resistance at 0° C. of a wire one metre long, weighing one gram. | Resistance at 0° C. of a wire one foot long, 1000 in. in diam. | Resistance at 0° C. of a wire one foot long, weighing one grain. | Percentage increase of resistance for 1° C. increase of temp. at 20° C. |
|--|---|--|--|--|--|---|

SPECIFIC RESISTANCE OF METALS.

TABLE 307 (concluded).

The resistance is here given as the resistance in microhms per cm. cube when the specific resistance of mercury at 0° C. is taken as 94.1 microhms.

| Substance.          | State.   | Temperature, C. | Resistance. | Authority.                     |

TABLE 308. — Temperature Resistance Coefficients.

If  $R_0$  is the resistance at the temperature  $t_0$ , and  $R_t$  at the temperature  $t$ , then  $R_t$  may over small ranges of temperature be approximately represented by the formula  $R_t = R_0 (1 + at)$ .

## CONDUCTING POWER OF ALLOYS.

This table shows the conducting power of alloys and the variation of the conducting power with temperature.\* The values of  $C_0$  were obtained from the original results by assuming silver =  $\frac{10^6}{1.585}$  mhos. The conductivity is taken as  $C_t = C_0 (1 - at + bt^2)$ , and the range of temperature was from  $0^\circ$  to  $100^\circ$  C.

The table is arranged in three groups to show (1) that certain metals when melted together produce a solution which has a conductivity equal to the mean of the conductivities of the components, (2) the behavior of those metals alloyed with others, and (3) the behavior of the other metals alloyed together.

It is pointed out that, with a few exceptions, the percentage variation between  $0^\circ$  and  $100^\circ$  can be calculated from the formula  $P' = P_c \frac{t}{100}$ , where  $t$  is the observed and  $P'$  the calculated conducting power of the mixture at  $100^\circ$  C., and  $P_c$  is the calculated mean variation of the metals mixed.

| Alloys.                                     | Weight %<br>of first named. | Volume % | $C_0$<br>$10^4$ | $a \times 10^6$ | $b \times 10^9$ | Variation per $100^\circ$ C. |             |

NOTE. — Barus, in the "Am. Jour. of Sci." vol. 36, has pointed out that the temperature variation of platinum alloys containing less than 10% of the other metal can be nearly expressed by an equation  $y = \frac{z}{x} - m$ , where  $y$  is the temperature coefficient and  $x$  the specific resistance,  $m$  and  $z$  being constants. If  $a$  be the temperature coefficient at  $0^\circ$  C. and  $s$  the corresponding specific resistance,  $s(a + m) = z$ .

For platinum alloys Barus's experiments gave  $m = -.000194$  and  $z = .0378$ .

For steel  $m = -.000303$  and  $z = .0620$ .

Matthiessen's experiments reduced by Barus gave for

Gold alloys  $m = -.000045$ ,  $z = .00721$ .

Silver "  $m = -.000112$ ,  $z = .00538$ .

Copper "  $m = -.000386$ ,  $z = .00055$ .

\* From the experiments of Matthiessen and Vogt, "Phil. Trans. R. S." v. 154.

Preece gives as formula for fusion of bare wires  $I = ad^{\frac{3}{2}}$ , where d = diam. in inches, a for cu. is 10,244; al., 7585; pt., 5172; German silver, 5230; platinoid, 4750; Fe, 3148; Pb., 1379; alloy 2 pts. Pb., 1 of Sn., 1318.

## RESISTANCE OF METALS AND

The electrical resistance of some pure metals and of some alloys have been determined by Dewar and Fleming and increases as the temperature is lowered. The resistance seems to approach zero for the pure metals, but not for temperature tried. The following table gives the results of Dewar and Fleming.\*

When the temperature is raised above 0° C. the coefficient decreases for the pure metals, as is shown by the experiments to be approximately true, namely, that the resistance of any pure metal is proportional to its absolute is greater the lower the temperature, because the total resistance is smaller. This rule, however, does not even zero Centigrade, as is shown in the tables of resistance of alloys. (Cf. Table 262.)

| Temperature =   | 100°                                   | 20°                    | 0°                     | - 80°                  |

† This is given by Dewar and Fleming as 13777 for 96°.4, which appears from the other measurements too high.

## ALLOYS AT LOW TEMPERATURES.

by Cailletet and Bouty at very low temperatures. The results show that the coefficient of change with temperature the alloys. The resistance of carbon was found by Dewar and Fleming to increase continuously to the lowest

ments or Müller, Benoit, and others. Probably the simplest rule is that suggested by Clausius, and shown by these temperature. This gives the actual change of resistance per degree, a constant; and hence the percentage of change approximately hold for alloys, some of which have a negative temperature coefficient at temperatures not far from

| Temperature =   | - 100°                                 | - 182°                 | - 197° | Mean value of temperature coefficient between - 100° and + 100° C.* |

\* The Steel Wire Gage is the same gage which has been known by the various names: "Washburn and Moen," "Roebing," "American Steel and Wire Co.s." Its abbreviation should be written "Stl. W. G.," to distinguish it from "S. W. G.," the usual abbreviation for the (British) Standard Wire Gage.

Taken from Circular No. 31. Copper Wire Tables, U.S. Bureau of Standards which contains more complete tables.

## WIRE TABLES.

TABLE 316.—Introduction. Mass and Volume Resistivity of Copper and Aluminum.

The following wire tables are abridged from those prepared by the Bureau of Standards at the request and with the cooperation of the Standards Committee of the American Institute of Electrical Engineers (Circular No. 31 of the Bureau of Standards). The standard of copper resistance used is "The International Annealed Copper Standard" as adopted Sept. 5, 1913, by the International Electrotechnical Commission and takes the Resistivity at 20° C. of an annealed copper wire one meter long weighing one gram as equal to 0.15328 ohm. This standard corresponds to a conductivity of  $58. \times 10^{-5}$  cgs. units, and a density of 8.89, at 20° C.

In the various units of mass and volume resistivity this may be stated as

|                                     |
|-------------------------------------|
| 0.15328 ohm (meter, gram) at 20° C. |
| 875.20 ohms (mile, pound) at 20° C. |
| 1.7241 microhm-cm. at 20° C.        |
| 0.67879 microhm-inch at 20° C.      |
| 10.371 ohms (mil, foot) at 20° C.   |

The temperature coefficient for this particular resistivity is  $a_{20} = 0.00393$  or  $a_0 = 0.00427$ . However, the temperature coefficient is proportional to the conductivity, and hence the change of resistivity per degree C. is a constant, 0.000597 ohm (meter, gram). The "constant mass" temperature coefficient of any sample is

$$a_t = \frac{0.000597 + 0.000005}{\text{resistivity in ohms (meter, gram) at } t^\circ \text{ C.}}$$

The density is 8.89 grams per cubic centimeter at 20° C., which is equivalent to 0.3212 pounds per cubic inch.

The values in the tables are for annealed copper of standard resistivity. The user of the tables must apply the proper correction for copper of other resistivity. Hard-drawn copper may be taken as about 2.7 per cent higher resistivity than annealed copper.

The aluminum tables are based on a figure for the conductivity published by the U. S. Bureau of Standards, which is the result of many thousands of determinations by the Aluminum Company of America. A volume resistivity of 2.828 microm-cm., and a density of 2.70 may be considered to be good average values for commercial hard-drawn aluminum. These values give :

|   |        |
|---|--------|
| Mass resistivity, in ohms (meter, gram) at 20° C. . . . . | 0.0764 |
| " " " " (mile, pound) at 20° C. . . . .                   | 436.   |
| Mass per cent conductivity . . . . .                      | 200.7% |
| Volume resistivity, in microm-cm. at 20° C. . . . .       | 2.828  |
| " " in microhm-inch at 20° C. . . . .                     | 1.113  |
| Volume per cent conductivity . . . . .                    | 61.0%  |
| Density, in grams per cubic centimeter . . . . .          | 2.70   |
| Density, in pounds per cubic inch . . . . .               | 0.0975 |

## SMITHSONIAN TABLES.

WIRE TABLES.

TABLE 317.—Temperature Coefficients of Copper for Different Initial Temperatures (Centigrade) and Different Conductivities.

| Ohms (meter, gram) at 20° C. | Per cent conductivity. | $\alpha_0$ | $\alpha_{15}$ | $\alpha_{20}$ | $\alpha_{25}$ | $\alpha_{30}$ | $\alpha_{50}$ |
|------------------------------|------------------------|------------|---------------|---------------|---------------|---------------|---------------|

| .159 60                      | 96%                    | .004 08    | .003 85       | .003 77       | .003 70       | .003 64       | .003 39       |
| .158 02                      | 97%                    | .004 13    | .003 89       | .003 81       | .003 74       | .003 67       | .003 42       |
| .157 53                      | 97.3%                  | .004 14    | .003 90       | .003 82       | .003 75       | .003 68       | .003 43       |
| .156 40                      | 98%                    | .004 17    | .003 93       | .003 85       | .003 78       | .003 71       | .003 45       |
| .154 82                      | 99%                    | .004 22    | .003 97       | .003 89       | .003 82       | .003 74       | .003 48       |
| .153 28                      | 100%                   | .004 27    | .004 01       | .003 93       | .003 85       | .003 78       | .003 52       |
| .151 70                      | 101%                   | .004 31    | .004 05       | .003 97       | .003 89       | .003 82       | .003 55       |

NOTE.—The fundamental relation between resistance and temperature is the following:

$$R_t = R_{t_1}(1 + \alpha_{t_1}[t - t_1]),$$

where  $\alpha_{t_1}$  is the "temperature coefficient," and  $t_1$  is the "initial temperature" or "temperature of reference."

The values of  $\alpha$  in the above table exhibit the fact that the temperature coefficient of copper is proportional to the conductivity. The table was calculated by means of the following formula, which holds for any per cent conductivity,  $n$ , within commercial ranges, and for centigrade temperatures. ( $n$  is considered to be expressed decimally: e.g., if per cent conductivity = 99 per cent,  $n = 0.99$ .)

$$\alpha_{t_1} = \frac{1}{\frac{1}{n(0.00393)} + (t_1 - 20)}$$

TABLE 318.—Reduction of Observations to Standard Temperature. (Copper.)

| Temperature C. | Corrections to reduce Resistivity to 20° C. |             |                    |               | Factors to reduce Resistance to 20° C. |                               |                                | Temperature C. |

This table for longer spark lengths contains the results of Voege, Ann. der Phys. 14, 1904, using alternating current and "dull point" electrodes, and the results with steady potential found in the recent very careful work of C. Müller, Ann. d. Phys. 28, p. 585, 1909.

The specially constructed electrodes for the columns headed "cup electrodes" had the form of a projecting knob 3 cm. in diameter and having a height of 4.5 mm. and 1.5 mm. respectively, attached to the plane face of the electrodes. These electrodes give a very satisfactory linear relation between the spark lengths and the voltage throughout the range studied.

TABLE 326. — Effect of the Pressure of the Gas on the Dielectric Strength.

Voltagcs are given for different spark lengths *l*.

| Pressure, cm. Hg. | <i>l</i> =0.04 | <i>l</i> =0.06 | <i>l</i> =0.08 | <i>l</i> =0.10 | <i>l</i> =0.20 | <i>l</i> =0.30 | <i>l</i> =0.40 | <i>l</i> =0.50 |

| .3                   | 10250                                | 9450  | 7450  | 4600  |
| .4                   | 11750                                | 10750 | 9100  | 5600  |
| .5                   | 13050                                | 12400 | 11000 | 6900  |
| .6                   | 14000                                | 13550 | 12250 | 8250  |
| .8                   | 15500                                | 15100 | 13850 | 10450 |
| 1.0                  | 16750                                | 16400 | 15250 | 12350 |

Determinations of the dielectric strength of the same substance by different observers do not agree well. For a discussion of the sources of error see Mościcki, *Electrotechn. Z.* 25, 1904.

For more detailed information on the dependence of the sparking distance in oils as a function of the nature of the electrodes, see Edmondson, *Phys. Review* 6, p. 65, 1898.

**TABLE 329.** — Electrical Resistance of Straight Wires with Alternating Currents of Different Frequencies.

This table gives the ratio of the resistance of straight copper wires with alternating currents of different frequencies to the value of the resistance with direct currents.

| Diameter of wire in millimeters. | Frequency $n =$ |        |       |        |        |         |

| 100                              | 3.31            | 4.19   |       |        |        |         |

Values between 1.000 and 1.001 are indicated by \*1.001.

The change of resistance of wires other than copper (iron wires excepted) may be calculated from the above table, making use of the fact that the change of resistance is a function of the argument  $p = 2\pi r\sqrt{2n\lambda}$  where  $r =$  radius of cross-section,  $n =$  frequency,  $\lambda =$  conductivity.

If a given wire be wound into a solenoid, its resistance, at a given frequency, will be greater than the values in the table, which apply to straight wires only. The resistance in this case is a complicated function of the pitch and radius of the winding, the frequency, and the diameter of the wire, and is found by experiment to be sometimes as much as twice the value for a straight wire.

**TABLE 330.** — Electrical Resistance for High Frequencies.

For which the high frequency resistance will be less than 1 per cent greater than direct current resistance.

Advance wire is practically identical electrically with constantan, while for high resistance German silver the values are nearly the same as for manganin. The column of the table under maximum current gives the approximate current which may be carried by the various sizes without undue heating. The current capacity of the manganin is very nearly the same.

From Austin, Jour. Wash. Acad. of Sci. 2, p. 190, 1911.

## WIRELESS TELEGRAPHY.

## Radiation Resistances for Various Wave-Lengths and Antenna Heights.

The radiation theory of Hertz shows that the radiated energy of an oscillator may be represented by  $E = \text{constant} (h^2/\lambda^2) I^2$ , where  $h$  is the length of the oscillator,  $\lambda$ , the wave-length and  $I$  the current at its center. For a flat-top antenna  $E = 1600 (h^2/\lambda^2) I^2$  watts;  $1600 h^2/\lambda^2$  is called the radiation resistance.

( $h$  = height to center of capacity of conducting system.)

Austin, Jour. Wash. Acad. of Sci. 1, p. 190, 1911.

**INTERNATIONAL ATOMIC WEIGHTS. ELECTROCHEMICAL  
EQUIVALENTS.**

The International Atomic Weights are quoted from the report of the International Committee on Atomic Weights (Journal American Chemical Society, 35, p. 1807, 1913).

The Electrochemical equivalent of Silver is 0.0011180 gram. sec.<sup>-1</sup> amp.<sup>-1</sup>. (See definition of International Ampere, p. xxxiii.) The electrochemical equivalent for any other element is

$$\frac{\text{atomic weight element}}{\text{atomic weight silver}} \times \frac{.0011180}{\text{valency}} \text{ gm. sec.}^{-1} \text{ amp.}^{-1}.$$

The equivalent for iodine has been recently (1913) determined at the Bureau of Standards as 1.3150. The valencies given are only those commonly shown by the elements.

## CONDUCTIVITY OF ELECTROLYTIC SOLUTIONS.

This subject has occupied the attention of a considerable number of eminent workers in molecular physics, and a few results are here tabulated. It has seemed better to confine the examples to the work of one experimenter, and the tables are quoted from a paper by F. Kohlrausch,\* who has been one of the most reliable and successful workers in this field.

The study of electrolytic conductivity, especially in the case of very dilute solutions, has furnished material for generalizations, which may to some extent help in the formation of a sound theory of the mechanism of such conduction. If the solutions are made such that per unit volume of the solvent medium there are contained amounts of the salt proportional to its electrochemical equivalent, some simple relations become apparent. The solutions used by Kohlrausch were therefore made by taking numbers of grams of the pure salts proportional to their electrochemical equivalent, and using a liter of water as the standard of quantity of the solvent. Taking the electrochemical equivalent number as the chemical equivalent or atomic weight divided by the valence, and using this number of grams to the liter of water, we get what is called the normal or gram molecule per liter solution. In the table,  $m$  is used to represent the number of gram molecules to the liter of water in the solution for which the conductivities are tabulated. The conductivities were obtained by measuring the resistance of a cell filled with the solution by means of a Wheatstone bridge alternating current and telephone arrangement. The results are for 18° C., and relative to mercury at 0° C., the cell having been standardized by filling with mercury and measuring the resistance. They are supposed to be accurate to within one per cent of the true value.

The tabular numbers were obtained from the measurements in the following manner:—

Let  $K_{18}$  = conductivity of the solution at 18° C. relative to mercury at 0° C.

$K_{18}^w$  = conductivity of the solvent water at 18° C. relative to mercury at 0° C.

Then  $K_{18} - K_{18}^w = k_{18}$  = conductivity of the electrolyte in the solution measured.

$\frac{k_{18}}{m} = \mu$  = conductivity of the electrolyte in the solution per molecule, or the "specific molecular conductivity."

TABLE 334.—Value of  $k_{18}$  for a few Electrolytes.

This short table illustrates the apparent law that the conductivity in very dilute solutions is proportional to the amount of salt dissolved.

| $m$      | KCl   | NaCl  | AgNO <sub>3</sub> | KC <sub>2</sub> H <sub>3</sub> O <sub>2</sub> | K <sub>2</sub> SO <sub>4</sub> | MgSO <sub>4</sub> |

If the quantities in Table 336 be represented by curves, it appears that the values of the specific molecular conductivities tend toward a limiting value as the solution is made more and more dilute. Although these values are of the same order of magnitude, they are not equal, but depend on the nature of both the ions forming the electrolyte.

When the numbers in Table 337 are multiplied by Hittorf's constant, or 0.00011, quantities ranging between 0.14 and 0.10 are obtained which represent the velocities in millimetres per second of the ions when the electromotive force gradient is one volt per millimetre.

Specific molecular conductivities in general become less as the concentration is increased, which may be due to mutual interference. The decrease is not the same for different salts, but becomes much more rapid in salts of high valence.

Salts having acid or alkaline reactions show marked differences. They have small specific molecular conductivity in very dilute solutions, but as the concentration is increased the conductivity rises, reaches a maximum and again falls off. Kohlrausch does not believe that this can be explained by impurities. H<sub>3</sub>PO<sub>4</sub> in dilute solution seems to approach a monobasic acid, while H<sub>2</sub>SO<sub>4</sub> shows two maxima, and like H<sub>3</sub>PO<sub>4</sub> approaches in very weak solution to a monobasic acid.

Kohlrausch concludes that the law of independent migration of the ions in media like water is sustained.

TABLE 338. — Temperature Coefficients.

The temperature coefficient in general diminishes with dilution, and for very dilute solutions appears to approach a common value. The following table gives the temperature coefficient for solutions containing 0.01 gram molecule of the salt.

| Salt.                           | Temp. Coeff. | Salt.   | Temp. Coeff. | Salt.   | Temp. Coeff. | Salt.  | Temp. Coeff. |

### THE EQUIVALENT CONDUCTIVITY OF SALTS, ACIDS AND BASES IN AQUEOUS SOLUTIONS.

In the following table the equivalent conductance is expressed in reciprocal ohms. The concentration is expressed in milli-equivalents of solute per litre of solution at the temperature to which the conductance refers. (In the cases of potassium hydrogen sulphate and phosphoric acid the concentration is expressed in milli-formula-weights of solute,  $KHSO_4$  or  $H_3PO_4$ , per liter of solution, and the values are correspondingly the modal, or "formal," conductances.) Except in the cases of the strong acids the conductance of the water was subtracted, and for sodium acetate, ammonium acetate and ammonium chloride the values have been corrected for the hydrolysis of the salts. The atomic weights used were those of the International Commission for 1905, referred to oxygen as 16.00. Temperatures are on the hydrogen gas scale.

Concentration in  $\frac{\text{gram equivalents}}{1000 \text{ liter}}$   
 Equivalent conductance in  $\frac{\text{reciprocal ohms per centimeter cube}}{\text{gram equivalents per cubic centimeter}}$

| Substance.                   | Concentration. | Equivalent conductance at the following °C temperatures. |         |         |         |       |       |       |       |      |        |

TABLE 344. — Variation of the Dielectric Constant with the Temperature.

For variation with the pressure see next table.

If  $D_\theta$  = the dielectric constant at the temperature  $\theta^\circ$  C.,  $D_t$  at the temperature  $t^\circ$  C., and  $\alpha$  and  $\beta$  are quantities given in the following table, then

$$D_\theta = D_t [1 - \alpha(t - \theta) + \beta(t - \theta)^2].$$

The temperature coefficients are due to Bädeker.

| Gas.            | $\alpha$              | $\beta$               | Range of temp. ° C. |
|-----------------|-----------------------|-----------------------|---------------------|
| Ammonia . .     | $5.45 \times 10^{-6}$ | $2.59 \times 10^{-7}$ | 10 — 110            |
| Sulphur dioxide | $6.19 \times 10^{-6}$ | $1.86 \times 10^{-7}$ | 0 — 110             |
| Water vapor .   | $1.4 \times 10^{-4}$  | -                     | 145                 |

The dielectric constant of air at atmospheric pressure but with varying temperature may also be calculated from the fact that  $D - 1$  is approximately proportional to the density.

TABLES 345, 346.  
DIELECTRIC CONSTANTS (continued).

TABLE 345.—Change of the Dielectric Constant of Gases with the Pressure.

PERMEABILITY OF IRON.

TABLE 352. — Permeability of Iron Rings and Wire.

This table gives, for a few specimens of iron, the magnetic induction  $B$ , and permeability  $\mu$ , corresponding to the magneto-motive forces  $H$  recorded in the first column. The first specimen is taken from a paper by Rowland,\* and refers to a welded and annealed ring of "Burden's Best" wrought iron. The ring was 6.77 cms. in mean diameter, and the bar had a cross sectional area of 0.916 sq. cms. Specimens 2-4 are taken from a paper by Bosanquet,† and also refers to soft iron rings. The mean diameters were 21.5, 22.1, and 22.725 cms., and the thickness of the bars 2.535, 1.295, and .7544 cms. respectively. These experiments were intended to illustrate the effect of thickness of bar on the induction. Specimen 5 is from Ewing's book,‡ and refers to one of his own experiments on a soft iron wire .077 cms. diameter and 30.5 cms. long.

| $H$   | Specimen 1 |       | 2     |       | 3     |       | 4     |       | 5     |       | NOTE. — The comparatively high value of the magnetizing force required for maximum permeability when the specimen is a thin drawn wire is noticeable in specimen 5. |

TABLE 353. — Permeability of Transformer Iron.§

This table contains the results of some experiments on transformers of the Westinghouse and Thomson-Houston types. Referring to the headings of the different columns,  $M$  is the total magneto-motive force applied to the iron;  $M/l$  the magneto-motive force per centimetre length of the iron circuit;  $B$  the total induction through the magnetizing coil;  $B/a$  the induction per square centimetre of the mean section of the iron core;  $M/B$  the magnetic reluctance of the iron circuit;  $Bl/Ma$  the permeability of the iron,  $a$  being taken as the mean cross section of the iron circuit as it exists in the transformer, which is thus slightly greater than the actual cross section of the iron.

E. Gumlich, Zs. für Electrochemie, 15, p. 599; 1909.

Brackets indicate annealing at 800° C in vacuum.

Parentheses indicate hardening by quenching from cherry-red.

B. O. Peirce, Proc. Am. Acad. 44, 1909.

TABLE 356. — Corrections for Ring Specimens.

In the case of ring specimens, the average magnetizing force is not the value at the mean radius, the ratio of the two being given in the table. The flux density consequently is not uniform, and the measured hysteresis is less than it would be for a uniform distribution. This ratio is also given for the case of constant permeability, the values being applicable for magnetizations in the neighborhood of the maximum permeability. For higher magnetizations the flux density is more uniform, for lower it is less, and the correction greater.

| Ratio of Radial Width to Diameter of Ring. | Ratio of Average H to H at Mean Radius. |                         | Ratio of Hysteresis for Uniform Distribution to Actual Hysteresis. |                         |

## COMPOSITION AND MAGNETIC

This table and Table 358 below are taken from a paper by Dr. Hopkinson \* on the magnetic properties of iron and steel, which is stated in the paper to have been 240. The maximum magnetization is not tabulated; but as stated in the by 47. "Coercive force" is the magnetizing force required to reduce the magnetization to zero. The "demagnetizing previous magnetization in the opposite direction to the "maximum induction" stated in the table. The "energy which, however, was only found to agree roughly with the results of experiment.

## PROPERTIES OF IRON AND STEEL.

The numbers in the columns headed "magnetic properties" give the results for the highest magnetizing force used, paper, it may be obtained by subtracting the magnetizing force (240) from the maximum induction and then dividing netizing force " is the magnetizing force which had to be applied in order to leave no residual magnetization after dissipated " was calculated from the formula:— Energy dissipated = coercive force  $\times$  maximum induction  $\div$   $\pi$

| No. of Test. | Description of specimen.             | Temper.                   | Specific electrical resistance. | Magnetic properties. |                     |                 |                      | Energy dissipated per cycle. |

## PERMEABILITY OF SOME OF THE SPECIMENS IN TABLE 357.

TABLE 358.

This table gives the induction and the permeability for different values of the magnetizing force of some of the specimens in Table 357. The specimen numbers refer to the same table. The numbers in this table have been taken from the curves given by Dr. Hopkinson, and may therefore be slightly in error; they are the mean values for rising and falling magnetizations.

| Magnetizing force.<br><i>H</i> | Specimen 1 (iron). |       | Specimen 8 (annealed steel). |       | Specimen 9 (same as 8 tempered). |       | Specimen 3 (cast iron). |       |

Tables 359-363 give the results of some experiments by Du Bois,\* on the magnetic properties of iron, nickel, and cobalt under strong magnetizing forces. The experiments were made on ovoids of the metals 18 centimeters long and 0.6 centimeters diameter. The specimens were as follows: (1) Soft Swedish iron carefully annealed and having a density 7.52. (2) Hard English cast steel yellow tempered at 230° C.; density 7.78. (3) Hard drawn best nickel containing 99% Ni with some SiO<sub>2</sub> and traces of Fe and Cu; density 8.82. (4) Cast cobalt giving the following composition on analysis: Co = 03.1, Ni = 5.8, Fe = 0.8, Cu = 0.2, Si = 0.1, and C = 0.3. The specimen was very brittle and broke in the lathe, and hence contained a surfaced joint held together by clamps during the experiment. Referring to the columns, *H*, *B*, and  $\mu$  have the same meaning as in the other tables, *S* is the magnetic moment per gram, and *I* the magnetic moment per cubic centimeter. *H* and *S* are taken from the curves published by Du Bois; the others have been calculated using the densities given.

\* "Phil. Mag." 5 series, vol. xxix.

† The results in this and the other tables for forces above 1200 were not obtained from the ovoids above referred to, but from a small piece of the metal provided with a polished mirror surface and placed, with its polished face normal to the lines of force, between the poles of a powerful electromagnet. The induction was then inferred from the rotation of the plane of a polarized ray of red light reflected normally from the surface. (See Kerr's "Constants," p. 331.)

| 2000  | 350 | 10084 | 5.0  |
| 12000 | 350 | 20084 | 1.7  |

Professor Ewing has investigated the effects of very intense fields on the induction in iron and other metals.† The results show that the intensity of magnetization does not increase much in iron after the field has reached an intensity of 1000 c. g. s. units, the increase of induction above this being almost the same as if the iron were not there, that is to say,  $dB/dH$  is practically unity. For hard steels, and particularly manganese steels, much higher forces are required to produce saturation. Hadfield's manganese steel seems to have nearly constant susceptibility up to a magnetizing force of 10,000. The following tables, taken from Ewing's papers, illustrate the effects of strong fields on iron and steel. The results for nickel and cobalt do not differ greatly from those given above.

**TABLE 368.—MAGNETIC PROPERTIES OF IRON IN VERY WEAK FIELDS.**

The effect of very small magnetizing forces has been studied by C. Baur\* and by Lord Rayleigh.† The following short table is taken from Baur's paper, and is taken by him to indicate that the susceptibility is finite for zero values of  $H$  and for a finite range increases in simple proportion to  $H$ . He gives the formula  $k = 15 + 100 H$ , or  $I = 15 H + 100 H^2$ . The experiments were made on an annealed ring of round bar 1.013 cms. radius, the ring having a radius of 6.432 cms. Lord Rayleigh's results for an iron wire not annealed give  $k = 6.4 + 5.1 H$ , or  $I = 6.4 H + 5.1 H^2$ . The forces were reduced as low as 0.00004 c. g. s., the relation of  $k$  to  $H$  remaining constant.

| First experiment. |       |        | Second experiment. |       |
|-------------------|-------|--------|--------------------|-------|
| $H$               | $k$   | $I$    | $H$                | $k$   |
| .01580            | 16.46 | 2.63   | .0130              | 15.50 |

**TABLES 369, 370.—DISSIPATION OF ENERGY IN CYCLIC MAGNETIZATION OF MAGNETIC SUBSTANCES.**

When a piece of iron or other magnetic metal is made to pass through a closed cycle of magnetization dissipation of energy results. Let us suppose the iron to pass from zero magnetization to strong magnetization in one direction and then gradually back through zero to strong magnetization in the other direction and thence back to zero, and this operation to be repeated several times. The iron will be found to assume the same magnetization when the same magnetizing force is reached from the same direction of change, but not when it is reached from the other direction. This has been long known, and is particularly well illustrated in the permanency of hard steel magnets. That this fact involves a dissipation of energy which can be calculated from the open loop formed by the curves giving the relation of magnetization to magnetizing force was pointed out by Warburg ‡ in 1881, reference being made to experiments of Thomson, § where such curves are illustrated for magnetism, and to E. Cohn, || where similar curves are given for thermoelectricity. The results of a number of experiments and calculations of the energy dissipated are given by Warburg. The subject was investigated about the same time by Ewing, who published results somewhat later. ¶ Extensive investigations have since been made by a number of investigators.

**TABLE 369.—Soft Iron Wire.**

(From Ewing's 1885 paper.)

| Total induction per sq. cm. $B$ | Dissipation of energy in ergs per cu. cm. | Horse-power wasted per ton at 100 cycles per sec. |

## DEMAGNETIZING FACTORS FOR RODS.

TABLE 371.

$H$  = true intensity of magnetizing field,  $H'$  = intensity of applied field,  $I$  = intensity of magnetization,  $H = H' - NI$ .

Shuddemagen says: The demagnetizing factor is not a constant, falling for highest values of  $l$  to about  $1/7$  the value when unsaturated; for values of  $B$  ( $=H + 4\pi I$ ) less than 10000,  $N$  is approximately constant; using a solenoid wound on an insulating tube, or a tube of split brass, the reversal method gives values for  $N$  which are considerably lower than those given by the step-by-step method; if the solenoid is wound on a thick brass tube, the two methods practically agree.

| Ratio of Length to Diameter. | Values of $N \times 10^4$ . |                        |                               |                        |   |     |      |

### DISSIPATION OF ENERGY IN THE CYCLIC MAGNETIZATION OF VARIOUS SUBSTANCES.

C. P. Steinmetz concludes from his experiments\* that the dissipation of energy due to hysteresis in magnetic metals can be expressed by the formula  $e = \alpha B^{1.6}$ , where  $e$  is the energy dissipated and  $\alpha$  a constant. He also concludes that the dissipation is the same for the same range of induction, no matter what the absolute value of the terminal inductions may be. His experiments show this to be nearly true when the induction does not exceed  $\pm 15000$  c. g. s. units per sq. cm. It is possible that, if metallic induction only be taken, this may be true up to saturation; but it is not likely to be found to hold for total inductions much above the saturation value of the metal. The law of variation of dissipation with induction range in the cycle, stated in the above formula, is also subject to verification.†

#### Values of Constant $\alpha$ .

The following table gives the values of the constant  $\alpha$  as found by Steinmetz for a number of different specimens. The data are taken from his second paper.

| Number of specimen. | Kind of material.  | Description of specimen.   | Value of $\alpha$ .   |
|---------------------|--------------------|--|---|
| 1                   | Iron . . .         | Norway iron . . . . .  | .00227  |

## ENERGY LOSSES IN TRANSFORMER STEELS.

Determined by the wattmeter method.

Loss per cycle per cc =  $AB^2 + bnB^3$ , where  $B$  = flux density in gausscs and  $n$  = frequency in cycles per second.  $x$  shows the variation of hysteresis with  $B$  between 5000 and 10000 gausscs, and  $y$  the same for eddy currents.

| Designation.   | Thick-ness. cm. | Ergs per Gramme per Cycle. |                      |               |                      | $x$  | $y$  | $a$     | Watts per Pound at 60 Cycles and 10000 Gausscs. |              |        |

‡ In order to make a fair comparison, the eddy current loss has been computed for a thickness of 0.0357 cm. (Gage No. 29), assuming the loss proportional to the thickness.

Lloyd and Fisher, Bull. Bur. Standards, 5, p. 453; 1909.

Note. — For formulae and tables for the calculation of mutual and self inductance see Bulletin Bureau of Standards, vol. 8, p. 1-237, 1912.

SMITHSONIAN TABLES.

## MAGNETO-OPTIC ROTATION.

Faraday discovered that, when a piece of heavy glass is placed in magnetic field and a beam of plane polarized light passed through it in a direction parallel to the lines of magnetic force, the plane of polarization of the beam is rotated. This was subsequently found to be the case with a large number of substances, but the amount of the rotation was found to depend on the kind of matter and its physical condition, and on the strength of the magnetic field and the wave-length of the polarized light. Verdet's experiments agree fairly well with the formula —

$$\theta = cIH \left( r - \lambda \frac{dr}{d\lambda} \right) \frac{r^2}{\lambda^2},$$

where  $c$  is a constant depending on the substance used,  $l$  the length of the path through the substance,  $H$  the intensity of the component of the magnetic field in the direction of the path of the beam,  $r$  the index of refraction, and  $\lambda$  the wave-length of the light in air. If  $H$  be different, at different parts of the path,  $lH$  is to be taken as the integral of the variation of magnetic potential between the two ends of the medium. Calling this difference of potential  $v$ , we may write  $\theta = Av$ , where  $A$  is constant for the same substance, kept under the same physical conditions, when the one kind of light is used. The constant  $A$  has been called "Verdet's constant,"\* and a number of values of it are given in Tables 376–380. For variation with temperature the following formula is given by Bichat: —

$$R = R_0 (1 - 0.00104t - 0.000014t^2),$$

which has been used to reduce some of the results given in the table to the temperature corresponding to a given measured density. For change of wave-length the following approximate formula, given by Verdet and Becquerel, may be used: —

$$\frac{\theta_1}{\theta_2} = \frac{\mu_1^2(\mu_1^2 - 1)\lambda_2^2}{\mu_2^2(\mu_2^2 - 1)\lambda_1^2},$$

where  $\mu$  is index of refraction and  $\lambda$  wave-length of light.

A large number of measurements of what has been called molecular rotation have been made, particularly for organic substances. These numbers are not given in the table, but numbers proportional to molecular rotation may be derived from Verdet's constant by multiplying in the ratio of the molecular weight to the density. The densities and chemical formulæ are given in the table. In the case of solutions, it has been usual to assume that the total rotation is simply the algebraic sum of the rotations which would be given by the solvent and dissolved substance, or substances, separately; and hence that determinations of the rotary power of the solvent medium and of the solution enable the rotary power of the dissolved substance to be calculated. Experiments by Quincke and others do not support this view, as very different results are obtained from different degrees of saturation and from different solvent media. No results thus calculated have been given in the table, but the qualitative result, as to the sign of the rotation produced by a salt, may be inferred from the table. For example, if a solution of a salt in water gives Verdet's constant less than 0.0130 at 20° C., Verdet's constant for the salt is negative.

The table has been for the most part compiled from the experiments of Verdet,† H. Becquerel,‡ Quincke,§ Koepsel,|| Arons,¶ Kundt,\*\* Jahn,†† Schönrock,‡‡ Gordon,§§ Rayleigh and Sidgewick,|||| Perkin,¶¶ Bichat,\*\*\*

As a basis for calculation, Verdet's constant for carbon disulphide and the sodium line  $D$  has been taken as 0.0420 and for water as 0.0130 at 20° C.

\* The constancy of this quantity has been verified through a wide range of variation of magnetic field by H. E. J. G. Du Bois (Wied. Ann. vol. 33, p. 137, 1888).

Du Bois shows that in the case of substances like iron, nickel, and cobalt which have a variable magnetic susceptibility the expression in Verdet's equation, which is constant for substances of constant susceptibility, requires to be divided by the susceptibility to obtain a constant. For this expression he proposes the name "Kundt's constant." These experiments of Kundt and Du Bois show that it is not the difference of magnetic potential between the two ends of the medium, but the product of the length of the medium and the induction per unit area, which controls the amount of rotation of the beam.

TABLE 380. — Verdet's and Kundt's Constants.

The following short table is quoted from Du Bois' paper. The quantities are stated in c. g. s. measure, circular measure (radians) being used in the expression of "Verdet's constant" and "Kundt's constant."

| Name of substance.          | Magnetic susceptibility. | Verdet's constant.        |             | Wave-length of light in cms. | Kundt's constant. |
|-----------------------------|--------------------------|---------------------------|-------------|------------------------------|-------------------|

TABLE 381. — Values of Kerr's Constant.\*

Du Bois has shown that the rotation of the major axis of vibration of radiations normally reflected from a magnet is algebraically equal to the normal component of magnetization multiplied into a constant  $K$ . He calls this constant  $K$ , Kerr's constant for the magnetized substance forming the magnet.

| Color of light.  | Spectrum line. | Wave-length in cms. $\times 10^6$ | Kerr's constant in minutes per c. g. s. unit of magnetization. |         |         |            |

## MAGNETIC SUSCEPTIBILITY.

If  $\mathfrak{M}$  is the intensity of magnetization produced in a substance by a field strength  $\mathfrak{H}$ , then the magnetic susceptibility  $H = \mathfrak{M}/\mathfrak{H}$ . This is generally referred to the unit mass; italicized figures refer to the unit volume. The susceptibility depends greatly upon the purity of the substance, especially its freedom from iron. The mass susceptibility of a solution containing  $p$  per cent by weight of a water-free substance is, if  $H_0$  is the susceptibility of water,  $(p/100) H + (1 - p/100) H_0$ .

| Iron         | }                        | Different specimens show very diverse results, usually an increase in weak fields, a decrease in strong. | Grummach, l. c.                     |
| Nickel steel |                          |  | Alloys behave similarly to iron.    |

TABLE 388. — Transverse Galvanomagnetic and Thermomagnetic Effects.

Effects are considered positive when, the magnetic field being directed away from the observer, and the primary current of heat or electricity directed from left to right, the upper edge of the specimen has the higher potential or higher temperature.

$E$  = difference of potential produced;  $T$  = difference of temperature produced;  $I$  = primary current;  $\frac{dt}{dx}$  = primary temperature gradient;  $B$  = breadth, and  $D$  = thickness, of specimen;  $H$  = intensity of field. C. G. S. units.

Hall effect (Galvanomagnetic difference of Potential),  $E = R \frac{HI}{D}$

Etingshausen effect ( " " " Temperature),  $T = P \frac{HI}{D}$

Nernst effect (Thermomagnetic " " Potential),  $E = QHB \frac{dt}{dx}$

Leduc effect ( " " " Temperature),  $T = SHB \frac{dt}{dx}$

RÖNTGEN (X-RAYS) RAYS.

Röntgen rays are produced whenever an electric discharge passes through a highly exhausted tube. The disturbance is propagated in straight lines probably with the velocity of light, affects photographic plates, excites phosphorescence, ionizes gases and suffers neither deviation by magnetic forces nor measurable refraction in passing through media of different densities. With extreme exhaustion in the tube they have an appreciable effect after passing through several millimeters of brass or iron. The quality by which it is best to classify the rays is their hardness which is the greater the greater the exhaustion. It is conveniently measured by the amount of absorption which they suffer in passing through a layer of aluminum or tin foil of standard thickness. The number of ions which the rays produce in 1 sec. in passing through 1 cu. cm. of a gas depends upon its nature and pressure. The absorption of any substance is equal to the sum of the absorption of the individual molecules and the absorption due to any molecule is independent of the nature of the chemical compound of which it forms a part, of its physical state, and probably of its temperature.

TABLE 390. — Ionization due to Röntgen Rays in Various Gases.

| Gas.                 | Relative ionization. |                 | Density. |

Strutt, Proc. Roy. Soc. 72, p. 209, 1903; Eve, Phil. Mag. 8, p. 610, 1904.

When Röntgen rays pass through matter they produce secondary Röntgen rays as well as cathodic rays. The former are of two types: the first is like the original rays and may be regarded as scattered primary rays; the second type varies with the nature of the material struck and is independent of the primary rays. If the atomic weight of the material struck is less than that of Calcium then the first type alone is present. The higher the atomic weight of the material struck the more penetrating is the secondary radiation given out. This is shown in the following table where  $\lambda$  is the reciprocal of the distance (cm.) in Al. through which the rays must pass in order that their intensity is reduced to  $1/2.7$  of its original intensity.

TABLE 391. — Röntgen Secondary Rays.

| Element.      | Cr.  | Fe.  | Co.  | Ni.  | Cu.  | Zn.  | As.  | Se.  | Sr.  | Ag.  | Sn.  |
|---------------|------|------|------|------|------|------|------|------|------|------|------|
| Atomic weight | 52.  | 55.8 | 59.0 | 58.7 | 63.6 | 65.4 | 75.0 | 79.2 | 87.6 | 108. | 119. |
| $\lambda$     | 397. | 239. | 193. | 160. | 129. | 106. | 61.  | 51.  | 35.2 | 6.75 | 4.33 |

The secondary cathodic rays seem to be independent of the material struck and of the intensity of the original rays. The velocity of these secondary rays depends upon the hardness of the original rays. The following table gives the thickness in cm. of the gas at 760 mm., 0° C. necessary to reduce the energy of the cathodic rays to one half (t) as well as  $\lambda$  as above defined.

TABLE 392. — Röntgen Secondary Cathodic Rays.

## RÖNTGEN (X-RAYS) RAYS.

TABLE 393. — Mean Absorption Coefficients,  $\frac{\lambda}{d}$ 

If  $I_0$  be the intensity of a parallel beam of homogeneous radiation incident normally on a plate of absorbing material of thickness  $t$ , then  $I = I_0 e^{-\lambda x}$  gives the intensity  $I$  at the depth  $x$ . Because of the greater homogeneity of the secondary X-rays they were used in the determination of the following coefficients. The coefficients  $\lambda$  have been divided by the density  $d$ .

| Radiator. | Absorber. |      |      |      |      |      |      |      |      |        |        |

Barkla, Sadla, Phil. Mag. 17, p. 739, 1909.

TABLE 394. — X-Ray Spectra and Atomic Numbers.

Kaye has shown that an element excited by sufficiently rapid cathode rays emits characteristic Röntgen radiations. These have been analyzed and the wave-lengths obtained by Moseley (Phil. Mag. 27, p. 703, 1914) using a crystal of potassium ferrocyanide as a grating. The "K" series of elements shows 2 lines,  $\alpha$  and  $\beta$ , the "L" series several. The wave-lengths of the  $\alpha$  and  $\beta$  lines of each series are given in the following table.  $Q_K = (v/\frac{3}{4} v_0)^{\frac{1}{2}}$ ;  $Q_L = (v/\frac{5}{8} v_0)^{\frac{1}{2}}$  where  $v$  is the frequency of the  $\alpha$  line and  $v_0$  the fundamental Rydberg frequency. The atomic number for the K series =  $Q_K + 1$ ; for the L series =  $Q_L + 7.4$  approximately.  $v_0 = 3.29 \times 10^{15}$ .

| Element. | $\alpha$ line<br>$\lambda \times 10^8 \text{cm.}$ | $Q_K$ | Atomic<br>Number<br>N | $\beta$ line<br>$\lambda \times 10^8 \text{cm.}$ | Element. | $\alpha$ line<br>$\lambda \times 10^8 \text{cm.}$ | $Q_L$ | Atomic<br>Number<br>N | $\beta$ line<br>$\lambda \times 10^8 \text{cm.}$ |

Moseley's summary condensed is as follows: Every element from Al to Au is characterized by an integer  $N$  which determines its X-ray spectrum;  $N$  is identified with the number of positive units of electricity in its atomic nucleus. The order of these atomic numbers ( $N$ ) is that of the atomic weights except where the latter disagrees with the order of the chemical properties. Known elements correspond with all the numbers between 13 and 79 except 3. There are here 3 possible elements still undiscovered. The frequency of any line in the X-ray spectrum is approximately proportional to  $A(N-b)^2$ , where  $A$  and  $b$  are constants. All X-ray spectra of each series are similar in structure differing only in wave-lengths.

Radioactivity is a property of certain elements of high atomic weight. It is an additive property of the atom, dependent only on it and not on the chemical compound formed nor affected by physical conditions controlling ordinary reactions, viz: temperature, whether solid or liquid or gaseous, etc.

With the exception of actinium, radioactive bodies emit  $\alpha$ ,  $\beta$ , or  $\gamma$  rays.  $\alpha$  rays are easily absorbed by thin metal foil or a few cms. of air and are positively charged atoms of helium emitted with about  $1/15$  the velocity of light. They are deflected but very slightly by intense electric or magnetic fields. The  $\beta$  rays are on the average more penetrating, are negatively charged particles projected with nearly the velocity of light, easily deflected by electric or magnetic fields and identical in type with the cathode rays of a vacuum tube. The  $\gamma$  rays are extremely penetrating and non-deviable, analogous in many respects to the very penetrating Röntgen rays. These rays produce ionization of gases, act on the photographic plate, excite phosphorescence, produce certain chemical reactions such as the formation of ozone or the decomposition of water. All radioactive compounds are luminous even at the temperature of liquid air.

Table 398 is based very greatly on Rutherford's Radioactive Substances and their radiations (Oct. 1912). To this and to Landolt-Börnstein Physikalisch-chemische Tabellen the reader is referred for references. In the three radioactive series each successive product (except  $\text{U. Y.}$  and  $\text{Ra. C}_2$ ) results from the transformation of the preceding product and in turn produces the following. When the change is accompanied by the ejection of an  $\alpha$  particle (helium, atomic weight = 4.0) the atomic weight decreases by 4. The italicized atomic weights are thus computed. Each product with its radiation decays by an exponential law; the product and its radiation consequently depend on the same law.  $I = I_0 e^{-\lambda t}$  where  $I_0$  = radioactivity when  $t = 0$ ,  $I$  that at the time  $t$ , and  $\lambda$  the transformation constant. Radioactive equilibrium of a body with its products exists when that body is of such long period that its radiation may be considered constant and the decay and growth of its products are balanced.

International radium standard: As many radioactivity measures depend upon the purity of the radium used, in 1912 a committee appointed by the Congress of Radioactivity and Electricity, Brussels, 1910, compared a standard of 21.99 mg. of pure Ra. chloride sealed in a thin glass tube and prepared by Mme. Curie with similar standards by Hönlischmid and belonging to The Academy of Sciences of Vienna. The comparison showed an agreement of 1 in 300. Mme. Curie's standard was accepted and is preserved in the Bureau international des poids et mesures at Sèvres, near Paris. Arrangements have been made for the preparation of duplicate standards for governments requiring them.

TABLE 395. — Relative Phosphorescence Excited by Radium.

(Becquerel, C. R. 129, p. 912, 1899.)

|   |       |                                 |     |
|---|-------|---------------------------------|-----|
| Without screen, Hexagonal zinc blende . . . . . | 13.36 | With screen . . . . .           | .04 |
| " " Pt. cyanide of barium . . . . .             | 1.99  | " " " " " " " " " " " " " " " " | .05 |
| " " Diamond . . . . .                           | 1.14  | " " " " " " " " " " " " " " " " | .01 |
| " " Double sulphate Ur and K . . . . .          | 1.00  | " " " " " " " " " " " " " " " " | .31 |
| " " Calcium fluoride . . . . .                  | .30   | " " " " " " " " " " " " " " " " | .02 |

The screen of black paper absorbed most of the  $\alpha$  rays to which the phosphorescence was greatly due. For the last column the intensity without screen was taken as unity. The  $\gamma$  rays have very little effect.

TABLE 396. — The Production of  $\alpha$  Particles (Helium).

(Geiger and Rutherford, Philosophical Magazine, 20, p. 691, 1910.)

| Radioactive substance (1 gram.)                | $\alpha$ particles per sec. | Helium per year.              |
|--|-----------------------------|-------------------------------|

In determining the above values the rays were first passed through one cm. of lead.

Russell and Soddy, Philosophical Magazine, 21, p. 130, 1911.

## RADIOACTIVITY.

TABLE 402. — Total Number of Ions produced by the  $\alpha$ ,  $\beta$ , and  $\gamma$  Rays.

The total number of ions per second due to the complete absorption in air of the  $\beta$  rays due to 1 gram of radium is  $9 \times 10^{14}$ , to the  $\gamma$  rays,  $13 \times 10^{14}$ .

The total number of ions due to the  $\alpha$  rays from 1 gram of radium in equilibrium is  $2.56 \times 10^{16}$ . If it be assumed that the ionization is proportional to the energy of the radiation, then the total energy emitted by radium in equilibrium is divided as follows: 92.1 parts to the  $\alpha$ , 3.2 to the  $\beta$ , 47 to the  $\gamma$  rays. (Rutherford, Moseley, Robinson.)

TABLE 403. — Amount of Radium Emanation. Curie.

At the Radiology Congress in Brussels in 1910, it was decided to call the amount of emanation in equilibrium with 1 gram of pure radium one Curie. [More convenient units are the millicurie ( $10^{-3}$  Curie) and the microcurie ( $10^{-6}$  Curie)]. The rate of production of this emanation is  $1.24 \times 10^{-9}$  cu. cm. per second. The volume in equilibrium is 0.59 cu. mm. (760 cm.,  $0^{\circ}$ C.) assuming the emanation mon-atomic.

The Mache unit is the quantity of Radium emanation without disintegration products which produces a saturation current of  $10^{-8}$  unit in a chamber of large dimensions. 1 curie =  $2.5 \times 10^9$  Mache units.

The amount of the radium emanation in the air varies from place to place; the amount per cubic centimeter of air expressed in terms of the number of grams of radium with which it would be in equilibrium varies from  $24 \times 10^{-12}$  to  $350 \times 10^{-12}$ .

TABLE 404. — Vapor Pressure of the Radium Emanation in cms. of Mercury.

(Rutherford and Ramsay, Phil. Mag. 17, p. 723, 1909, Gray and Ramsay, Trans. Chem. Soc. 95, p. 1073, 1909.)

# APPENDIX.

## DEFINITIONS OF UNITS.

**ACTIVITY.** Power or rate of doing work; unit, the watt.

**AMPERE.** Unit of electrical current. The international ampere, "which is one tenth of the unit of current of the C. G. S. system of electro-magnetic units, and which is represented sufficiently well for practical use by the unvarying current which, when passed through a solution of nitrate of silver in water, and in accordance with accompanying specifications" (see pages xxxvi, 261), "deposits silver at the rate of 0.001118 of a gram per second."

The ampere = 1 coulomb per second = 1 volt through 1 ohm =  $10^{-1}$  E. M. U. =  $3 \times 10^9$  E. S. U.\*

Amperes = volts/ohms = watts/volts = (watts/ohms) $^{\frac{1}{2}}$ .

Amperes  $\times$  volts = amperes $^2$   $\times$  ohms = watts.

**ANGSTROM.** Unit of wave-length =  $10^{-10}$  meter.

**ATMOSPHERE.** Unit of pressure.

English normal = 14.7 pounds per sq. in. = 29.929 in. = 760.18 mm. Hg. 32° F.

French " = 760 mm. of Hg. 0° C. = 29.922 in. = 14.70 lbs. per sq. in.

**BOUGIE DECIMALE.** Photometric standard; see page 178.

**BRITISH THERMAL UNIT.** Heat required to raise one pound of water at its temperature of maximum density, 1° F. = 252 gram-calories.

**CALORY.** Small calory = gram-calory = therm = quantity of heat required to raise one gram of water at its maximum density, one degree Centigrade.

Large calory = kilogram-calory = 1000 small calories = one kilogram of water raised one degree Centigrade at the temperature of maximum density.

For conversion factors see page 237.

**CANDLE.** Photometric standard, see page 178.

**CARAT.** The diamond carat standard in U. S. = 200 milligrams. Old standard = 205.3 milligrams = 3.168 grains.

The gold carat: pure gold is 24 carats; a carat is  $1/24$  part.

**CARCEL.** Photometric standard; see page 178.

**CIRCULAR AREA.** The square of the diameter =  $1.2733 \times$  true area.

True area =  $0.785398 \times$  circular area.

**COULOMB.** Unit of quantity. The international coulomb is the quantity of electricity transferred by a current of one international ampere in one second. =  $10^{-1}$  E. M. U. =  $3 \times 10^9$  E. S. U.

Coulombs = (volts-seconds)/ohms = amperes  $\times$  seconds.

**CUBIT** = 18 inches.

**DAY.** Mean solar day. = 1440 minutes = 86400 seconds = 1.0027379 sidereal day.

Sidereal day = 86164.10 mean solar seconds.

**DIGIT.**  $3/4$  inch;  $1/12$  the apparent diameter of the sun or moon.

**DIOPTER.** Unit of "power" of a lens. The number of diopters = the reciprocal of the focal length in meters.

**DYNE.** C. G. S. unit of force = that force which acting for one second on one gram produces a velocity of one centimeter per second.

= weight in grams divided by the acceleration of gravity in cm. per sec.

**ELECTROCHEMICAL EQUIVALENT** is the ratio of the mass in grams deposited in an electrolytic cell by an electrical current to the quantity of electricity.

**ENERGY.** See Erg.

**ERG.** C. G. S. unit of work and energy = one dyne acting through one centimeter.

For conversion factors see page 237.

**FARAD.** Unit of electrical capacity. The international farad is the capacity of a condenser charged to a potential of one international volt by one international coulomb of electricity. =  $10^{-9}$  E. M. U. =  $9 \times 10^{11}$  E. S. U.

The one-millionth part of a farad (microfarad) is more commonly used.

Farads = coulombs/volts.

\* E. M. U. = C. G. S. electromagnetic units. E. S. U. = C. G. S. electrostatic units.

FOOT-POUND. The work which will raise one pound one foot high.

For conversion factors *see* page 237.

FOOT-POUNDAIS. The English unit of work = foot-pounds/g.

For conversion factors *see* page 237.

g. The acceleration produced by gravity.

GAUSS. A unit of intensity of magnetic field = 1 E. M. U. =  $\frac{1}{3} \times 10^{-10}$  E. S. U.

GRAM. *See* page 6.

GRAM-CENTIMETER. The gravitation unit of work = g. ergs.

GRAM-MOLECULE, =  $x$  grams where  $x$  = molecular weight of substance.

GRAVITATION CONSTANT =  $G$  in formula  $G \frac{m_1 m_2}{r^2} = 666.07 \times 10^{-10}$  cm.<sup>3</sup>/gr. sec.<sup>2</sup>

For further conversion factors *see* page 237.

HEAT OF THE ELECTRIC CURRENT generated in a metallic circuit without self-induction is proportional to the quantity of electricity which has passed in coulombs multiplied by the fall of potential in volts, or is equal to (coulombs  $\times$  volts)/4.181 in small calories.

The heat in small or gram-calories per second = (amperes<sup>2</sup>  $\times$  ohms)/4.181 = volts<sup>2</sup>/ (ohms  $\times$  4.181) = (volts  $\times$  amperes)/4.181 = watts/4.181.

HEAT. Absolute zero of heat = -273.13° C, -459.6° Fahrenheit, -218.5° Reaumur.

HEFNER UNIT. Photometric standard; *see* page 178.

HENRY. Unit of induction. It is "the induction in a circuit when the electromotive force induced in this circuit is one international volt, while the inducing current varies at the rate of one ampere per second." = 10<sup>9</sup> E. M. U. =  $\frac{1}{3} \times 10^{-11}$  E. S. U.

HORSE-POWER. The practical unit of power = 33,000 pounds raised one foot per minute. = 550ft. pds. per sec. = 0.746 kilowatt = 746 watts.

JOULE. Unit of work = 10<sup>7</sup> ergs.

Joules = (volts<sup>2</sup>  $\times$  seconds)/ohms = watts  $\times$  seconds = amperes<sup>2</sup>  $\times$  ohms  $\times$  sec.

For conversion factors *see* page 237.

JOULE'S EQUIVALENT. The mechanical equivalent of heat = 4.185  $\times 10^7$  ergs. *See* page 227.

KILODYNE. 1000 dynes. About 1 gram.

LITER. *See* page 6.

LUMEN. Unit of flux of light-candles divided by solid angles.

MEGABAR. Unit of pressure = 0.987 atmospheres.

MEGADYNE. One million dynes. About one kilogram.

METER. *See* page 6.

METER CANDLE. The intensity lumination due to standard candle distant one meter.

MHO. The unit of electrical conductivity. It is the reciprocal of the ohm.

MICRO. A prefix indicating the millionth part.

MICROFARAD. One millionth of a farad, the ordinary measure of electrostatic capacity.

MICRON. ( $\mu$ ) = one millionth of a meter.

MIL. One thousandth of an inch.

MILE. *See* pages 5, 6.

MILE NAUTICAL or GEOGRAPHICAL = 6080.204 feet.

MILLI-. A prefix denoting the thousandth part.

MONTH. The anomalistic month = time of revolution of the moon from one perigee to another = 27.55460 days.

The nodical month = draconitic month = time of revolution from a node to the same node again = 27.21222 days.

The sidereal month = the time of revolution referred to the stars = 27.32166 days (mean value), but varies by about three hours on account of the eccentricity of the orbit and "perturbations."

The synodic month = the revolution from one new moon to another = 29.5306 days (mean value) = the ordinary month. It varies by about 13 hours.

OHM. Unit of electrical resistance. The international ohm is based upon the ohm equal to 10<sup>9</sup> units of resistance of the C. G. S. system of electromagnetic units, and "is represented by the resistance offered to an unvarying electric current by a column of mercury, at the temperature of melting ice, 14.4521 grams in mass, of a constant cross section and of the length of 106.3 centimeters." = 10<sup>9</sup> E. M. U. =  $\frac{1}{3} \times 10^{-11}$  E. S. U.

International ohm = 1.01367 B. A. ohms = 1.06292 Siemens' ohms.

B. A. ohm = 0.98651 international ohms.

Siemens' ohm = 0.94080 international ohms. *See* page 272.

PENTANE CANDLE. Photometric standard. *See* page 178.

$\pi$  = ratio of the circumference of a circle to the diameter = 3.14159265359.

POUNDAI. The British unit of force. The force which will in one second impart a velocity of one foot per second to a mass of one pound.

RADIAN = 180°/ $\pi$  = 57.29578° = 57° 17' 45" = 206265".

SECOHM. A unit of self-induction = 1 second  $\times$  1 ohm.

- THERM** = small calory = quantity of heat required to warm one gram of water at its temperature of maximum density one degree Centigrade.
- THERMAL UNIT, BRITISH** = the quantity of heat required to warm one pound of water at its temperature of maximum density one degree Fahrenheit = 252 gram-calories.
- VOLT**. The unit of electromotive force (E. M. F.). The international volt is "the electromotive force that, steadily applied to a conductor whose resistance is one international ohm, will produce a current of one international ampere, and which is represented sufficiently well for practical use by  $1000/1434$  of the electromotive force between the poles or electrodes of the voltaic cell known as Clark's cell, at a temperature of  $15^{\circ}$  C and prepared in the manner described in the accompanying specification." =  $10^8$  E. M. U. =  $1/300$  E. S. U. See pages xxxiv and 261.
- VOLT-AMPERE**. Equivalent to Watt/Power factor.
- WATT**. The unit of electrical power =  $10^7$  units of power in the C. G. S. system. It is represented sufficiently well for practical use by the work done at the rate of one Joule per second.
- Watts = volts  $\times$  amperes = amperes<sup>2</sup>  $\times$  ohms = volts<sup>2</sup>/ohms (direct current or alternating current with no phase difference).  
For conversion factors see page 237.
- Watts  $\times$  seconds = Joules.
- WEBER**. A name formerly given to the coulomb.
- YEAR**. See page 109.
- Anomalistic year = 365 days, 6 hours, 13 minutes, 48 seconds.  
Sidereal " = 365 " 6 " 9 " 9.314 seconds.  
Ordinary " = 365 " 5 " 48 " 46 + "  
Tropical " same as the ordinary year.

# INDEX.

For the definition of units, see Appendix.

|   | PAGE.    |  | PAGE.          |
|---|----------|--|----------------|
| $\alpha$ rays, absorptive powers for            | 340      | Boiling-point, raising of, by salts in solution  | 219            |
| definition and properties                       | 337      | of water and barometric pressure                 | 170            |
| Aberration constant                             | 109      | Brick, crushing strength of                      | 68             |
| Absorption coefficient: air                     | 181, 182 | Brightness of various lights                     | 178            |

     crystals . . . . . 185-190  
     fluorite . . . . . 186  
     gases and vapors . . . . . 193  
     glass . . . . . 184  
     Iceland spar . . . . . 186  
     liquids . . . . . 192  
     metals . . . . . 195-196  
     monorefringent solids . . . . . 188  
     nitroso-dimethyl-aniline . . . . . 186  
     quartz . . . . . 187  
     rock-salt . . . . . 185  
     salt solutions . . . . . 191  
     silvite . . . . . 185  
     solids, isotropic . . . . . 188
- Relative humidity . . . . . 160  
 Resistance: *see also* Conductivity.  
     alloys, low temperature . . . . . 280  
     alternating current, effect of . . . . . 297  
     aluminum . . . . . 284  
     copper . . . . . 284  
     electrolytic, *see* Conductivity.  
     glass and porcelain . . . . . 282  
     legal unit of . . . . . 272  
     magnetic field, of bismuth in . . . . . 333  
     metals in . . . . . 333  
     nickel in . . . . . 333  
     metals at low temperatures . . . . . 280  
     ohm, various determinations of . . . . . 272  
     platinum, thermometer . . . . . 247  
     radiation, wireless telegraphy . . . . . 300  
     specific: metals . . . . . 274-276  
     wires . . . . . 273, 286-293  
     temperature variation . . . . . 276, 280, 282, 285
- Rigidity, modulus of . . . . . 71  
     temperature variation . . . . . 71  
 Ring correction (magnetization) . . . . . 317  
 Rock-salt, indices of refraction . . . . . 185  
 Rods, demagnetizing factors for . . . . . 323  
 Röntgen rays . . . . . 335-336  
     ray spectra . . . . . 336  
 Rotation of polarized light: by solutions . . . . . 293  
 Rotation, magneto-optic: formula . . . . . 326  
     gases . . . . . 339  
     Kerr's constant . . . . . 331  
     liquids . . . . . 328  
     solids . . . . . 327  
     solutions . . . . . 329  
     Verdet's constant . . . . . 326-330
- Rowland's standard wave-lengths . . . . . 173
- Salts, lowering of freezing-point by . . . . . 227  
     raising " boiling- " " . . . . . 229  
 Saturation, magnetic, for steel . . . . . 321  
 Scales, musical . . . . . 103  
 Screens, color . . . . . 201-202  
 Seconds pendulum . . . . . 107  
 Secondary batteries . . . . . 263  
 Sections of wires . . . . . 283  
 Shearing tests of timber . . . . . 69-70  
 Sheet metal, weights of . . . . . 89  
 Silica glass specific heats . . . . . 240  
 Silver, electro-chemical equivalent . . . . . 261, 301  
 Silvite, indices of refraction . . . . . 185  
 Sines, natural and logarithmic, circular . . . . . 32-49  
     hyperbolic . . . . . 41-47  
 Sky-light, comparison with sunlight . . . . . 182  
 Soaring of planes, data for . . . . . 125  
 Solar constant of radiation . . . . . 181  
     distance from earth . . . . . 109  
     energy, data of . . . . . 181-183  
     motion . . . . . 110  
     parallax . . . . . 109  
     radiation monthly change . . . . . 183  
     spectrum . . . . . 181, 183  
     temperature . . . . . 181

# NEW SUBSPECIES OF MAMMALS FROM EQUATORIAL AFRICA

By EDMUND HELLER

NATURALIST, SMITHSONIAN AFRICAN EXPEDITION

Further study of the collection of mammals from British East Africa and Uganda now in the United States National Museum, secured by the Smithsonian African Expedition under the direction of Colonel Roosevelt and the Paul J. Rainey African Expedition, has brought to light the several new forms of carnivores and rodents described in the present paper.

## THOS

Jackals and Coyotes

The jackals and their American representatives the coyotes are separable from the true wolves, which are typical of the genus *Canis*, by several constant dental characters which seem to justify the recognition of the group under the generic name *Thos* first proposed by Oken in 1816 for the Indian jackal, *Canis aureus*. Oken placed four specific names under his group name *Thos*, the last of which, *Canis vulgaris*, he particularly mentions as being the *Thos* of the ancients and on this account it should stand as the type of the genus. *Canis vulgaris* is a synonym of *C. aureus*. *Thos* may be defined as a group of *Canidae* having long slender *Vulpes*-like canines, small outer incisors, small carnassials, upper molar teeth with well marked cingulums and the fourth lower premolar with a minute extra cusp on its hinder border. The genus *Canis* or the wolves are distinguishable by their much thicker and shorter canines; their greatly enlarged outer incisors which are more than twice the size of the inner ones, being somewhat hyena-like in this respect; large carnassial teeth; upper molars without a definite cingulum; and the fourth lower pre-molar without a third cusp on its posterior border.

East equatorial Africa or rather Northeast Africa generally is supplied with more species of jackals than any other region. Three distinct species are found living together on the same plains over most of the territory of British East Africa. The most distinct of the three species in coloration is the black-backed or *T. mesomelas* which has the black of the back sharply marked off from the bright rufous of the sides. The Indian species, *T. aureus*, which here reaches

its southern limit in Africa, approaches *mesomelas* closely in shape of skull and the large size of its reddish ears but differs by the broken character of its black dorsal area which merges indefinitely into the color of the sides. The best marked species of the three in skull characters is the side-striped jackal or *T. adustus* which has a long slender snout and very long *Vulpes*-like canine teeth. In body coloration, however, it is not always easily distinguishable from the Indian but it may be recognized with certainty by its small dark colored ears and the presence of a more or less well marked white tail tip. An excellent series consisting of 68 specimens of skins with their skulls are in the National Museum from British East Africa representing the three species referred to above. A comparison of this material shows several well marked forms occupying definite geographical or faunal areas. The races of African jackals thus far described have come from South Africa or from Abyssinia and the Sudan and none of the names thus far proposed seem to be applicable in a restricted sense to the East African races which are described in the following pages.

•

KEY TO THE RACES AND SPECIES OF JACKALS OCCURRING IN  
BRITISH EAST AFRICA

- A<sup>1</sup> Black of back not sharply defined against light color of sides; foreleg marked by a black stripe in front; chin dark brown or blackish in marked contrast to the light color of the throat.
- B<sup>1</sup> Sides marked by a more or less definite black stripe owing to the middle area of the back being vermiculated by whitish; back of ears dark brown; tip of tail usually showing some white hairs; snout long, the nasal bones extending as far posteriorly as the maxillaries or beyond; bony palate extending as far posteriorly as the posterior edge of the last molar.....*Thos adustus*
- C<sup>1</sup> Underparts ochraceous-rufous, the hair basally dark gray; tail with a few white hairs at tip or none.....*T. adustus brecha*
- C<sup>2</sup> Underparts white or pale buff, the hair uniform to the roots; tail broadly tipped by white .....*T. adustus notatus*
- B<sup>2</sup> Sides merging gradually into the dark color of the back; backs of the ears ochraceous; tail black tipped; snout short, the nasal bones not extending as far posteriorly as the maxillaries; bony palate not reaching as far posteriorly as last molar.....*T. aureus*
- C<sup>1</sup> Coloration lighter and body size less than in the northern races .....*T. aureus bea*
- A<sup>2</sup> Black of back sharply defined against light color of sides and uniform throughout; foreleg not marked by a black stripe; chin whitish and uniform with the throat in color; tail tip black; snout short, the nasal bones not extending posteriorly to the maxillaries; palate not reaching to end of tooth row .....*T. mesomelas*

B<sup>1</sup> Size larger; underparts ochraceous with dark hair bases

*T. mesomelas elgonae*

B<sup>2</sup> Size smaller; underparts white or light buff; the hair uniform to the roots ..... *T. mesomelas mcmillani*

**THOS ADUSTUS BWEHA**, new subspecies

Elgon Side-striped Jackal

*Type* from Kisumu, British East Africa; adult male, number 182342, U. S. Nat. Mus.; collected by Edmund Heller, January 20, 1912; original number 2663.

*Characters*.—The Elgon side-striped jackal, *Thos adustus bweha*, resembles most closely the Abyssinian race *kaffensis* described by Neumann from the headwaters of the Sobat River in southwestern Abyssinia. It may be distinguished from that race by the much darker color of the legs and the reddish character of the dorsal hair basally. From *notatus* it differs by the darker underparts which are washed with ochraceous-rufous, and are dark haired basally throughout. The legs are a deep russet heavily black lined on their upper parts, the hind quarters being especially deep and rich in coloring. The back is heavily black-lined and merges into the black of the sides so that the side-striped effect is quite obscured or absent entirely. The tail is not conspicuously white-tipped as in *notatus*, this feature being reduced to a few scattered white hairs hidden among the black hairs of the tip. The tail is shorter and the foot averages smaller than that of *notatus*. The flesh measurements of the type were: head and body, 720 mm.; tail, 310; hindfoot, 148; ear from notch, 90. Skull: condylo-incisive length, 152; greatest length, 160; zygomatic width, 82; interorbital width, 27; postorbital width, 30; nasals 13.4×58; length of upper cheek to front of canine, 68; width of mesopterygoid fossa, 14.5; length of palate, 80; length of incisive foramina, 10. The skull shows considerable age, the sagittal crest being a high knife-like ridge and the basisphenoidal sutures obliterated. This specimen is unfortunately somewhat abnormal having two pairs of upper carnassial teeth, the smaller pair being inside the larger.

The collection contains three additional adult males from the type locality and two from the Uasin Gishu Plateau. The latter are more heavily lined with black than those from the Kavirondo country, but otherwise are quite indistinguishable from them. Two skins and four skulls are in the National Museum from Mashonaland, which represent the Zambesi race *holubi*. These are distinguishable from

*bvcha* by their rufous-backed ears and their larger skulls and body size generally.

The Swahili name for the jackal and the one commonly adopted by the interior tribes now in touch with European civilization is *bvcha*. Distinctive names for the three species occurring together throughout the country do not appear to be in use among any of the tribes.

#### **THOS ADUSTUS NOTATUS, new subspecies**

##### Loita Side-striped Jackal

*Type* from the Loita Plains, British East Africa; young adult male, number 181486, U. S. Nat. Mus.; collected by Edmund Heller, April 16, 1911; original number 2033.

*Characters*.—*Thos adustus notatus* may be distinguished from all other races by its white underparts, the whole throat, chest and belly being white, the hair of the throat and chest being white to the roots but dark gray basally on the belly. From typical *adustus* of South Africa it may be further distinguished by its smaller size, the skull being decidedly smaller, by its drab instead of russet ears and the brighter rufous of the dorsal hair basally. It resembles *adustus* in the light color of its legs which are ochraceous-buff, the foreleg having a black stripe from the shoulder to the knee. The tail is conspicuously tipped by pure white as in *adustus*. It differs from *bvcha* of the Kavirondo and Uasin Gishu region by its light underparts, light colored legs, white tipped tail and distinctiveness of the black side stripe. The tail is considerably longer than in *bvcha* but the general body size is the same.

The flesh measurements of the type were: head and body, 715 mm.; tail, 390; hindfoot, 165; ear from notch, 80. Skull: condylo-incisive length, 152; greatest length, 157; zygomatic breadth, 80; interorbital width, 26.5; postorbital width, 30.5; nasals, 14×58; length of upper cheek teeth to outer edge of canine, 70; length of upper carnassial, 13.9; width of mesopterygoid fossa, 14.8; length of palate, 79. Skull somewhat immature with distinct sutures and lacking a sagittal crest.

Besides the type there is in the National Museum another adult male from the Loita Plains which resembles the type closely in color and an immature female from the same locality which shows a fulvous wash on the underparts, which may be a sexual color difference rather than individual in character. The type has been compared with two adult male specimens from south of the Zambesi River representing typical *adustus*.

**THOS AUREUS BEA**, new subspecies

## Southern Golden Jackal

*Type* from the Loita Plains, British East Africa; adult female, number 162904, U. S. Nat. Mus.; collected by Edmund Heller, July 4, 1909; original number, 200.

*Characters.*—*Thos aureus bea* may be distinguished from the more northern African races by its much smaller body size and lighter coloration generally, the ears and legs being of a decidedly lighter fulvous shade. Compared to *variegatus*, the Abyssinia race, the size is much less, the difference in skull length being 25 millimeters less. Typical *aureus* of India differs only racially from these North Africa jackals which have usually been treated as a race of *anthus* originally described from Senegal. In skull characters and coloration the African resembles the Indian and Asiatic races of *aureus* so closely that their relationship is better shown by placing them under the Indian jackal as subspecific forms. The present form is the most southern race and the only one to extend south of the equator. It doubtless reaches its extreme southern limit in central German East Africa but no specimens have yet been reported from that region. In a general way this jackal coincides, in its geographical range, with the striped hyena throughout Africa and Asia.

The type is an adult female in fresh pelage, the back being heavily lined or overlaid by black from the nape to the tip of the tail which is wholly black and has the hair everywhere basally vinaceous. The underparts are whitish or pale buff, the hair being uniform to the roots. The backs of the ears and the legs are bright ochraceous, the forelegs having a black stripe in front over the knee similar to the black stripe on *adustus*. Worn specimens often have the median area of the back lacking the black hair tips but the sides still retaining them, which produces a side-striped effect quite similar to the side-striped effect of *adustus*. Young and immature specimens lack the black lining of the back and are consequently much lighter colored than the adults.

The flesh measurements of the type were: head and body, 640 mm.; tail, 275; hindfoot, 140; ear from notch, 99. Skull: condylo-incisive length, 140; greatest length, 150; zygomatic breadth, 77; interorbital breadth, 23.5; postorbital constriction, 26; nasals, 13.2 × 53; length of upper cheek teeth including canine, 65; length of upper carnassial, 15.5; length of palate, 71; width of mesopterygoid fossa, 14; length of incisive foramina, 11.

Five specimens are in the National Museum from the plains north of Mount Kenia which mark the eastern limits of the Laikipia Plateau. Two additional specimens from the Loita Plains, one from the Rift Valley near Mount Suswa and another from Lake Naivasha complete the series.

**THOS MESOMELAS ELGONAE, new subspecies**

Highland Black-backed Jackal

*Type* from the Usin Gishu Plateau, British East Africa, altitude 8,000 feet; adult male, number 164699, U. S. Nat. Mus.; collected by Edmund Heller, November 13, 1909; original number, 466.

*Characters.*—*Thos mesomelas elgonae* resembles most closely the Athi or coast race *mcmillani* but may be distinguished from it by its darker coloration, larger size and heavier coat. The underparts are darker than those of the desert race, being ochraceous-buff, the hair basally being quite grayish and the sides are duller ochraceous-rufous. The tail is tipped with black and the backs of the ears are tawny. From *mesomelas* of South Africa this race differs by its less rufous underparts and absence of rufous on the head.

The type measured in the flesh: head and body, 600 mm.; tail, 325; hindfoot, 150; ear from notch, 100. Skull: condylo-incisive length, 141; greatest length, 145; zygomatic breadth, 84; interorbital width, 28.5; postorbital constriction, 30; nasals, 13×48; length of upper cheek teeth including canine, 62.5; length of palate, 70; width of mesopterygoid fossa, 14.3; length of upper carnassial, 16.5.

A series of 10 specimens are in the collection from the type locality, which agree with the type in the character of their ventral coloration and long heavy coat. This is a highland race confined apparently to the upper elevations of the Nile watershed.

**THOS MESOMELAS MCMILLANI, new subspecies**

Athi Black-backed Jackal

*Type* from Mtoto Andei station, British East Africa, altitude 2,500 feet; adult female, number 181483, U. S. Nat. Mus.; collected by Edmund Heller, April 5, 1911; original number 2003.

*Characters.*—*Thos mesomelas mcmillani* differs from typical *mesomelas* of South Africa by its smaller body size and less rufous coloration. The underparts are especially light, the throat and belly being white or pale buff instead of rufous as in *mesomelas* and the hair of these parts is light to the roots rather than grayish basally.

This race approaches in its light coloration closely *schmidti* of Somaliland but it differs from this form by the absence of rufous on the head and the white tipped tail. The tip of the tail is marked by a tuft of white hair, a feature not found in the series of 35 skins from the Loita Plains and the northern Guaso Nyiro districts, all of which have black tips. The type is in fresh pelage and has the black back well marked and sharply contrasted from the bright ochraceous-rufous sides and legs. The hair of the back basally is hair-brown of Ridgway. The backs of the large ears are ochraceous and the chin is white like the throat in color.

The flesh measurements were: head and body, 600 mm.; tail, 350; hindfoot, 140; ear from notch, 95. The skull shows considerable age and has a high, well developed sagittal crest. Condylar-incisive length, 137; greatest length, 146; zygomatic breadth, 82; interorbital width, 29.5; postorbital constriction, 31.5; nasals, 13.2×53; length of upper cheek teeth including canine, 62.5; length of palate, 67; width of mesopterygoid fossa, 15.5; length of upper carnassial, 15.

The type is unique in the possession of the distinct white tail tip but a large series (35) of specimens from the Loita Plains, the northern Guaso Nyiro district, Athi Plains and Taveta, Kilimanjaro district, which are closely similar to the type in their white underparts, have the tail black tipped. This race is confined to the coast drainage and the lower parts of the Rift Valley and is the only jackal which is found in the low desert nyika country.

Named for William N. McMillan to whom the Smithsonian African Expedition is indebted for his generous hospitality at Juja Farm and in Nairobi.

#### **HELIOSCIURUS RUFBRACHIATUS SHINDI, new subspecies**

Taiti Red-legged Squirrel

*Type* from the summit of Mount Umengo, Taita Hills, British East Africa, altitude, 6,000 feet; adult male, number 182768, U. S. Nat. Mus.; collected by Edmund Heller, November 11, 1911; original number 4731.

*Characters*.—Most closely related to *Heliosciurus rufobrachiatus undulatus* of Kilimanjaro but differing by having paler underparts, buffy-ochraceous in tone without the rufous cast of that form. The dorsal surface is lighter with less black lining than in *undulatus*. The feet differ by being ochraceous and never as dark as the rufous of *undulatus*. There are no apparent differences in size or proportion of parts.

The flesh measurements were: head and body, 225 mm.; tail, 283; hindfoot, 55; ear, 18. Skull; condylo-incisive length, 50; zygomatic breadth, 32; nasals, 18×8.2; interorbital width, 17; postorbital width, 16.5; length of upper tooth row, 11; diastema, 11.5.

This squirrel is confined to the remnant of forest covering the extreme summit of the Taita Hills, where it is very rare. The type was the only individual seen during a fortnight's stay on the summit of Umengo Mountain. It has been compared with the type of *undulatus* which was collected by Dr. L. W. Abbott on Mount Kilimanjaro and is now in the National Museum. Among the Wataita tribe this squirrel is known as "shindi."

**TATERA NIGRACAUDA PERCIVALI, new subspecies**

Lorian Black-tailed Gerbille

*Type* from the Lorian Swamp, British East Africa, altitude 700 feet; adult female, number 183945, U. S. Nat. Mus.; collected by A. Blayney Percival; original number 792.

*Characters*.—*Tatera nigracauda percivali* differs from the race *iconica* from the middle course of the Guaso Nyiro drainage by its duller or paler dorsal coloration, the reduction of black lining on the back and the smaller body size. The pelage throughout is much shorter and thinner, a condition brought about by the extremely arid and hot conditions of the Lorian desert which lies at an altitude of only 700 feet.

Flesh measurements: head and body, 133 mm.; tail, 170; hindfoot, 35; ear, 21. Skull: condylo-incisive length, 35.5; zygomatic breadth, 20; interorbital breadth, 8; nasals, 4×16.5; length of upper tooth row, 6.5; diastema, 10.8; length of incisive foramina, 7.8; mastoid breadth of skull, 18.2.

The type is the only specimen in the National Museum.

**EPIMYS KAISERI TURNERI, new subspecies**

Kavirondo Bush Rat

*Type* from Kisumu, British East Africa; adult female, number 183395, U. S. Nat. Mus.; collected by H. J. Allen Turner; original number 5121.

*Characters*.—Nearest in coloration to *Epimys kaiseri hindci* of the Athi River drainage but decidedly darker, the dorsal surface russet rather than ochraceous, the underparts gray instead of buff, and the

feet drab, not white as in the other East African races. From *medicatus* of Mumias it differs decidedly by its shorter tail, the tail being considerably less than the head and body while in the former it is much greater. The skull differs from that of *medicatus* by its more arched dorsal profile, longer snout, smaller size and greater concavity to the antorbital plate on its outer margin.

Flesh measurements of the type: head and body, 155 mm.; tail, 135; hindfoot, 27; ear, 22. Skull: condylo-incisive length, 35; zygomatic breadth, 19; interorbital breadth, 5.5; nasals,  $4.8 \times 16$ ; length of upper tooth row, 6.5; diastema, 10; length of incisive foramina, 8.5.

Ten specimens besides the type are in the collection from Kisumu where they were secured in the papyrus beds on the margin of Kavirondo Bay. This race appears to be confined to the papyrus beds of the Victoria Nyanza, the rising country immediately back of the lake being occupied by the long-tailed, light-colored *medicatus*.

Named for H. J. Allen Turner of Nairobi to whom the writer is indebted for much assistance in collecting mammal specimens throughout the Kavirondo country.

#### EPIMYS CONCHA ISMAILIAE, new subspecies

Gondokoro Multimammate Mouse

*Type* from Gondokoro, Uganda; adult male, number 165108, U. S. Nat. Mus.; collected by J. Alden Loring, February 23, 1910; original number 9056.

*Characters*.—This race is allied most closely to *Epimys concha blainci* of Chak-Chak, Bahr-el-Ghazal River, but may be distinguished by its larger feet and longer tail. The coloration is quite as in *blainci*, the dorsal surface being wood-brown slightly darker on the midline and the underparts are white, the hair basally dark gray.

The flesh measurements of the type were: head and body, 108 mm.; tail, 115; hindfoot, 24. Skull: Condylo-incisive length, 26.5; zygomatic breadth, 13.5; interorbital width, 4.1; nasals,  $3.4 \times 12$ ; length of upper tooth row, 4.7; diastema, 7.4; length of incisive foramina, 6.8.

A series of 20 specimens are in the National Museum. Ten of these are from the type locality and the others are from Nimule and the stations just north of it on the Gondokoro Road which follows the east bank of the Nile.

**EPIMYS KAISERI CENTRALIS**, new subspecies

## Nile Bush Rat

*Type* from Rhino Camp, Lado Enclave, British East Africa: adult male, number 165035, U. S. Nat. Mus.; collected by J. Alden Loring, January 11, 1910; original number 8633.

*Characters*.—The coloration of this race resembles closely that of *Epimys kaiseri norae* of the northern Guaso Nyiro drainage of British East Africa but differs by its less buffy tone to the dorsal surface and by the much shorter tail and wider skull.

Flesh measurements of the type were: head and body, 148 mm.; tail, 162; hindfoot, 30. Skull: condylo-incisive length, 35; zygomatic breadth, 19; interorbital width, 5.8; nasals,  $4.5 \times 1.5$ ; length of upper tooth row, 5.8; diastema, 10; length of incisive foramina, 9.

A series of 38 specimens are in the National Museum from Rhino Camp, Lado Enclave. Others somewhat less typical in character are from Unyoro, Uganda, and from Nimule and Gondokoro in northern Uganda.

**MUS GRATUS SORICOIDES**, new subspecies

## Taita Pygmy Mouse

*Type* from Mount Mbololo, Taita Hills, British East Africa: adult male, number 183544, U. S. Nat. Mus.; collected by Edmund Heller, November 8, 1911; original number 4675.

*Characters*.—Like *Mus gratus* of Ruwenzori but underparts much more buffy or rather ochraceous in tone. Body size somewhat less, both the feet and skull being smaller but the tail is longer. The dorsal color is bister-brown lined by black medially and bordered on the lower sides by an indefinite band of bright fulvous. The underparts are ochraceous, the hair basally gray. Feet buffy. This race is confined to the remnants of forest still left on the extreme summits of the Taita Hills at elevations of 5,000 or 6,000 feet. Two additional specimens are in the collection from Mbolobo Mountain and one other from Umengo Mountain.

Flesh measurements of the type: head and body, 60 mm.; tail, 59; hindfoot, 13; ear, 11. Skull: condylo-incisive length, 17.3; zygomatic breadth, 9.3; interorbital breadth, 3.5; nasals,  $2.3 \times 8.2$ ; length of upper tooth row, 3.3; diastema, 4.5; length of incisive foramina, 4.2.

**OENOMYS HYPOXANTHUS VALLICOLA**, new subspecies

Naivasha Rusty-nosed Rat

*Type* from Lake Naivasha, British East Africa; adult female, number 162614, U. S. Nat. Mus.; collected by J. Alden Loring, July 15, 1909; original number 6640.

*Characters*.—This is a much lighter and smaller race than *bacchante* of the Mau and Kikuyu escarpments bounding the Rift Valley to the west and the east of Naivasha. In coloration it approaches nearer *editus* of Ruwenzori but is less rufous or rusty and is somewhat smaller in body size. The skull is shorter decidedly than that of *editus* but equals it in zygomatic width.

Flesh measurements of the type: head and body, 160 mm.; tail, 184; hindfoot, 31. Skull: condylo-incisive length, 34; zygomatic breadth, 17; interorbital width, 5.5; nasals,  $4.6 \times 15$ ; length of upper tooth row, 7; diastema, 10; length of incisive foramina, 7.8.

Three other specimens from Naivasha are in the collection and they agree in coloration with the type.

**ARVICANTHIS ABYSSINICUS VIRESCENS**, new subspecies

Olivaceous Grass Rat

*Type* from Voi, British East Africa; adult male, number 183922, U. S. Nat. Mus.; collected by Edmund Heller, November 15, 1911; original number 4775.

*Characters*.—*Arvicanthis abyssinicus virescens* resembles *nairobae* most closely from which it may be readily distinguished by its darker dorsal coloration, which is heavily lined by blackish hairs having a distinct greenish iridescence. The body size is considerably smaller and the skull shows relatively smaller bulke, and teeth, and narrower and more slender nasal bones. In the tone of its dark dorsal coloration it resembles *nubilans* of the Kavirondo region but it differs from this race by its white underparts and its much smaller body size.

The flesh measurements were: head and body, 125 mm.; tail, 103; hindfoot, 26; ear, 16.5. Skull: condylo-incisive length, 30; zygomatic breadth, 16.8; interorbital breadth, 4.8; nasals,  $4.8 \times 12$ ; length of upper tooth row, 6.2; width of first upper molar, 2; diastema, 8.8; length of incisive foramina, 6.2.

The type is unique. It has been compared with a large series of topotypes of both *nairobae* and *nubilans* in the National Museum and is readily distinguishable from both of these races.

**LEMNISCOMYS DORSALIS MEARNSI, new subspecies**

Kikuyu Single-striped Grass Rat

*Type* from Fort Hall, British East Africa, altitude 6,200 feet; adult female, number 163616, U. S. Nat. Mus.; collected by J. Alden Loring, September 11, 1909; original number 7152.

*Characters*.—*Lemniscomys dorsalis mearnsi* is an intensely ferruginous form of *dorsalis* differing from the Taita race *maculosus* by richer coloring and larger size. The rump and hindlegs are bright ferruginous which, farther forward on the shoulders, becomes less intense and quite ochraceous in tone. The underparts are uniform white in sharp contrast to the bright ochraceous-rufous sides.

The flesh measurements of the type are: head and body, 131 mm.; tail, 140; hindfoot, 31; ear, 12. Skull: condylo-incisive length, 33; zygomatic breadth, 17; interorbital breadth, 5; nasals,  $4.4 \times 13$ ; length of upper tooth row, 6.5; diastema, 9.3; length of incisive foramina, 7.

Two other specimens from Fort Hall complete the series of this race which represents altitudinal as well as inland limits of this coast species.

**ACOMYS IGNITIS MONTANUS, new subspecies**

Marsabit Spiny Mouse

*Type* from the north slope of Mount Marsabit, British East Africa; altitude 4,600 feet; adult female; number 182901 U. S. Nat. Mus.; collected February 26, 1911, by A. Blayne Percival; original number, 309.

*Characters*.—Resembling *Acomys ignitus* in general features as well as in quality of the pelage but coloration much grayer and duller and size larger. Dorsal coloration vinaceous-drab, the sides brighter or pure vinaceous but not sharply marked from the darker mid-dorsal region. Underparts and feet pure white, the hair white to the roots. Tail and ears drab-gray.

Flesh measurements of the type: head and body, 90 mm.; tail, 92; hindfoot, 17; ear, 16.5. Skull wanting. Another topotype also with skull missing is in the collection. The race is a mountain form living at an elevation of 4,000 feet or more and is larger and duller colored than the low desert forms to which it is related all of which are confined to the lower desert levels below 2,500 feet in altitude.

# EXPLORATIONS AND FIELD-WORK OF THE SMITHSONIAN INSTITUTION IN 1913

## INTRODUCTION

There is here presented a general account of the exploration and field-work conducted by the Smithsonian Institution and its several branches, including the United States National Museum, in various parts of the world during the calendar year 1913. These explorations were made by means of allotments from the Smithsonian funds, from Congressional appropriations, and through the coöperation of other institutions and of individuals engaged or interested in geological, biological, or anthropological investigations.

The Institution and its branches were thus represented in a large number of field parties whose researches have tended to increase the general knowledge in various subjects, and have added much valuable material to the collections of the National Museum. Owing to its limited funds, the Institution was unable to participate in several additional enterprises in which opportunities for representation were offered.

In the preparation of the present account the direct statements of those who participated in the field-work have been employed, with one or two exceptions, while nearly all the photographs were made by the explorers themselves.

Some of the work carried on in 1913 was in continuation of operations begun in previous years and reported in part in accounts heretofore published by the Institution.<sup>1</sup>

Three Government branches of the Institution are represented in this report: The National Museum, although having no specific funds for exploration work, avails itself as far as possible of all opportunities presented for making collections in the field; the Bureau of American Ethnology engages largely in field-work, which is covered in detail in the annual report of that bureau; and the

Explorations and Field-Work of the Smithsonian Institution in 1912. Smithsonian Misc. Coll., Vol. 60, No. 30, 1913.

Astrophysical Observatory at times conducts special expeditions both in the United States and abroad, in connection with its regular work of studying the physical properties of the sun and their effect on the earth.

Both the National Museum and the National Zoological Park received during the year many donations and accessions presented or collected by collaborators in this country and abroad who have no official connection with either branch. The remaining branches under the Smithsonian Institution were not represented by any field parties, and therefore are not mentioned in this account.

Photograph taken while clouds and mist were drifting over the upper part of the peak. The summit of the peak is 8,800 feet above the camera. The view shows the southwest face of the peak. Photograph by C. D. Walcott, 1913.

#### GEOLOGICAL EXPLORATIONS IN THE CANADIAN ROCKIES

In continuation of his previous geological researches in the Canadian Rockies, Dr. Charles D. Walcott, Secretary of the Institution, revisited during the field season of 1913, the Robson Peak district in British Columbia and Alberta, and the region about Field, British Columbia. At the latter place he received the members of the International Geological Congress.

FIG. 2.—Robson Peak from a ridge above and north of east end of Berg Lake, showing north side of peak. Robson Park, British Columbia, Canada. Photograph by C. D. Walcott, 1913.

FIG. 3.—Hunga Glacier from south slope of Mumm Peak, with Phillips and other mountains to the south. Robson Park, British Columbia, Canada. Photograph by C. D. Walcott, 1913.

On this trip to Robson Peak, Dr. Walcott approached from the west side, in order to study the local geological section which he considers one of the finest in the world. From the west foot of Robson Peak, Whitehorn Peak rises on the north to a height of 7,850 feet above Lake Kinney (frontispiece), and on the east the cliffs of Robson rise tier above tier from the surface of the lake to the summit of the peak, a vertical distance of 9,800 feet. The base of this geo-

FIG. 4.—Phillips Mountain, from Robson Pass, looking over the front of Hunga Glacier. Robson Park, British Columbia, Canada. Photograph by C. D. Walcott, 1913.

logical section is shown on the right of the frontispiece, and the upper half by figure 1, while figure 2 illustrates a profile of 7,500 feet of the section.

From beneath the base of the mountain at Lake Kinney, the strata slope gently upward so that more than 4,000 feet in thickness of beds, which pass under Robson Peak, are exposed in ledges to the north and south. A considerable portion of this thickness is shown in the dark peak to the left of Whitehorn Peak in the frontispiece.

Owing to exceptionally good climatic conditions, the season of 1913 proved unusually favorable for viewing Robson Peak. Fre-

FIG. 5.—Brook entering Berg Lake, one mile southwest of Robson Pass. View taken about half a mile from the lake. Robson Park, British Columbia, Canada. Photograph by C. D. Walcott, 1913.

quently in the early morning the details of the snow slopes on the summit of the peak were beautifully outlined. Toward evening,

however, the mists driven in from the warm currents of the Pacific, 300 miles away, shrouded the mountain from view (fig. 7).

FIG. 6.—Camp on the north side of Robson Pass.  
Photograph by C. D. Walcott, 1913.

From the slopes of Titkana Peak, west of the great Hunga Glacier (figs. 3 and 4), a wonderful view is obtained of the snow fields and falling glaciers east of Robson Peak. The glacial streams come

FIG. 7.—View from Walcott Camp, looking westward over President Range after sunset when the mist is driving eastward over the mountains. Near Field, British Columbia, Canada. Photograph by C. D. Walcott, 1913.

FIG. 8.—Panoramic view of west side of foot of Hunga Glacier where the stream forming the head-waters of Grand Fork comes from beneath the ice and flows westward into Berg Lake. Robson Park, British Columbia, Canada. Photograph by C. D. Walcott, 1913.

FIG. 9.—View looking out from the fossil quarry over Burgess Pass, to the right of the mountain, the Van Horne Range in the distance, the President Range and Emerald Lake. On the left the Kicking Horse Valley, Mount Dennis, and in the distance Mount Vaux. Near Field, British Columbia, Canada. Photograph by C. D. Walcott, 1913.

FIG. 10.—North end of the fossil quarry above Burgess Pass on the slope of the ridge between Mount Wapta and Mount Field, 4,000 feet above sea level. Photograph by C. D. Walcott, 1913.

tumbling down the slopes (fig. 5) and often disappear beneath the glacier to reappear at its foot with the volume of a river (fig. 8).

At Field, British Columbia, work was continued at the great Cambrian fossil quarry, where a large collection of specimens was secured. The conditions were such that it was necessary to do much heavy blasting to reach the finest fossils which occur in the lower layers of rock. Figure 10 shows the north end of the quarry below the sharp

FIG. 11.—South end of fossil quarry, where many of the most beautiful specimens were secured from the lower three feet of beds. Near Field, British Columbia, Canada. Photograph by C. D. Walcott, 1913.

summit of Mount Wapta, and, in the distance, the President Range with Emerald Lake at its base. The south end of the quarry is illustrated by figure 11; here the solid beds were blasted out to a depth of 22 feet.

Owing to the presence of a fault line, just north of the quarry, and the twist and compression of the rocks south of it, the available area for successful collecting is limited to about 200 feet. In other localities where the shale outcrops on the ridges in the vicinity, com-

pression and shearing have so changed the character of the rock that it is impossible to obtain fossils in a condition to be of service.

The collections of 1913 contain a number of very important additions to this ancient Cambrian fauna, and many fine additional examples of species found in 1912.

FIG. 14.—Boulder train on the surface of the west side of Hunga Glacier, overlooking the Robson Pass, British Columbia. The Secretary of the Smithsonian Institution is standing beside the boulder. Photograph by Miss Helen B. Walcott, 1913.

#### GEOLOGIC HISTORY OF THE APPALACHIAN VALLEY IN MARYLAND

Dr. R. S. Bassler, curator of paleontology in the U. S. National Museum, spent a month during the summer of 1913, in the Appalachian Valley of Maryland and the adjoining States, studying the Postpaleozoic geologic history of the region, as indicated by the present surface features. His studies, which were under the joint auspices of the U. S. National Museum and the Maryland Geological Survey, were in continuation of work carried on during the previous summer when the sedimentary rocks of the region were mapped in detail, the final object being the preparation of a report on the Lower

Paleozoic strata of Maryland, to complete a series of memoirs published by that State. Owing to the brevity of this account, only a few points in the physiographic history will be noted here.

Since Carboniferous time western Maryland has been above the sea, and its rocks have accordingly been subjected to a long period of aerial erosion. During Jurassic time, the area remained stationary for so long a period that the surface of the land in the Appalachian province was reduced to a rolling plain. Later uplift raised this

FIG. 15.—Jurassic (Schooley) peneplain, preserved in the Blue Ridge of Maryland. Photograph by Bassler.

plain still higher above sea level, and in Maryland only remnants of the old surface are preserved in the flat skyline of the highest mountains. This ancient plain, or Schooley peneplain, as it is termed, is well preserved on the top of the Blue Ridge, as shown in figure 15.

A second great period of erosion occurred in early Tertiary time, the effects of which were chiefly in the Appalachian Valley proper, where the erosion is indicated by a pronounced plain at an elevation of about 750 feet. This plain was formed only on the softer Paleozoic rocks, and, because of its prominence near Harrisburg, Pennsylvania, is known as the Harrisburg peneplain. Conococheague Creek traverses the Harrisburg peneplain in Maryland, and has dissected it

considerably, as shown in figure 16, but the even skyline of the ancient plain is still clearly evident.

Other factors in the geologic history of Maryland are recorded in the well defined gravel terraces along the major streams of the area and in great alluvial fans of large and small bowlders, spreading out at the foot of the larger mountains and sometimes reaching a depth of 150 feet. All of these phenomena have been plotted and will form a part of the geologic map of the region.

FIG. 16.—Dissected Early Tertiary (Harrisburg) peneplain, west of Hagerstown, Maryland. Photograph by Bassler.

#### COLLECTING FOSSIL ECHINODERMS IN ILLINOIS

The special field explorations maintained by Mr. Frank Springer, associate in paleontology in the U. S. National Museum, were continued during the season of 1913 by his private collector, Frederick Braun. The purpose of these explorations is to obtain additional material for use in Mr. Springer's monographs upon the fossil crinoidea, now in course of preparation, but they also result in important accessions of excellent specimens for the completion of the exhibition series in the hall of Invertebrate Paleontology in the National Museum.

The investigations of the past summer were confined to the Kaskaskia rocks of Monroe and Randolph Counties, Illinois. They were systematically carried on in connection with the geological work for the State of Illinois, in progress at the same time under the direction of Professor Weller, in order to have the benefit of accurate determinations of the horizons from which the collections were made, with reference to the several subordinate formations into which the

FIG. 17.—Portion of a slab of fossil Crinoids from Illinois.  
Photograph by National Museum.

Kaskaskia of that region is divided. In this way it was hoped to rectify some confusion as to the stratigraphic relation of a number of species described in the Geological Reports of Illinois and Iowa. The operations were successful in this respect, and at the same time six large boxes of fine specimens were obtained. Among the specimens there are a number of slabs covered with Crinoids not hitherto found in that formation, in an excellent state of preservation. A portion of one slab, containing 22 specimens of 9 different species, is shown in the accompanying illustration (fig. 17). This specimen and

others of similar character, giving a complete representation of the Kaskaskia crinoidal fauna, are being prepared for installation in the exhibition hall of the National Museum.

#### FURTHER EXPLORATION OF THE CUMBERLAND PLEISTOCENE CAVE DEPOSIT

In May, 1913, Mr. J. W. Gidley, assistant curator of fossil mammals in the U. S. National Museum, made a second visit to the Pleistocene cave deposit near Cumberland, Maryland, which proved even

FIG. 18.—Near view of part of excavation made near Cumberland, Maryland, by U. S. National Museum party. Photograph by Armbruster.

more successful than the one of the previous year, reported in the account of the Smithsonian explorations of 1912.

Many new forms were added to the collection, and much better material was obtained of several species represented only by jaw fragments in the first collection. The collection now contains upward of 300 specimens, representing at least 40 distinct species of mammals, many of which are now extinct. Among the better preserved specimens are several nearly complete skulls and lower jaws. The more important animals represented are two species of bears, two species of a large extinct peccary, a wolverine, a badger, a martin, two porcupines, a woodchuck, and the American eland-like antelope.

FIG. 19.—View from opposite side of railroad cut showing fossil deposits at bottom, near track, and traces of ancient opening at top of cliff. Photograph by Armbruster.

These species are all new and, with the exception of the American eland, the dog, and one of the bears, which Mr. Gidley has already described,<sup>1</sup> have not yet been named.

Other species represented by more fragmentary material include the mastodon, tapir, horse, and beaver, besides several species of the smaller rodents, shrews, bats, and others.

This strange assemblage of fossil remains occurs hopelessly intermingled and comparatively thickly scattered through a more or less unevenly hardened mass of cave clays and breccias, which completely filled one or more small chambers of a limestone cave, the material together with the bones evidently having come to their final resting place through an ancient opening at the surface a hundred feet or more above their present location. The deposit is at present exposed at the bottom of a deep cut through which the Western Maryland Railroad has built its tracks. The railroad excavation first brought to light the ancient bone deposit and incidentally made access to the fossils comparatively easy. It is proposed to continue work on this important deposit during the next season.

#### A FOSSIL HUNTING EXPEDITION IN MONTANA

While engaged in Geological Survey work in northwestern Montana in 1912, Mr. Eugene Stebinger discovered a promising locality of vertebrate fossil remains. The following summer (1913), under the auspices of the U. S. Geological Survey, Mr. Charles W. Gilmore, assistant curator of fossil reptiles in the National Museum, headed an expedition for the purpose of obtaining, if possible, a representative collection from this area.

In July a camp was established on Milk River, some thirty-five miles north and west of Cut Bank, Montana, on the Blackfeet Indian Reservation. Four weeks were spent here in collecting, the work being confined entirely to the Upper Cretaceous (Belly River beds) as exposed in the bad-lands for ten miles along this stream. Later, in August, camp was moved some fifty miles south on the Two Medicine River, and two weeks were spent working in the same geological formation.

Taking into consideration the short time at the disposal of the party, the results of the expedition were most gratifying. Between

<sup>1</sup> Smithsonian Misc. Coll., Vol. 60, No. 27, 1913.

Proceedings U. S. National Museum, Vol. 40, No. 2014, 1913.

500 and 600 separate fossil bones were obtained, many of them of large size. The most notable discovery was a new Ceratopsian<sup>1</sup> or horned dinosaur, the smallest of its kind known. There were portions of five individuals of this animal recovered, representing nearly all parts of the skeleton, so that it will be possible to mount a composite skeleton for exhibition. In this connection, it is perhaps of interest to know that, although Ceratopsian fossils were first dis-

FIG. 20.—Fossil beds as exposed on Milk River, Montana. The small Ceratopsian dinosaur was found in the breaks in the foreground. Photograph by Gilmore.

covered in the Rocky Mountain region in 1855, and portions of a hundred or more skeletons have been collected, this is the first individual to be found having a complete articulated tail and hind foot. It thus contributes greatly to our knowledge of the skeletal anatomy of this interesting group of extinct reptiles.

Another noteworthy find was a partial skeleton of one of the Trachodont or duck-billed dinosaurs. This animal was only recently

<sup>1</sup>Mr. Gilmore's description of this extinct reptile is to be found in the Smithsonian Misc. Coll., Vol. 63, No. 3, 1914.

FIG. 21.—Fossil beds as exposed on Two Medicine River, Montana. Camp of fossil hunters in the foreground. Photograph by Gilmore.

FIG. 22.—Fossil leg bone of a dinosaur shown as found in the ground, on Milk River, Montana. Photograph by Stebinger.

described from specimens obtained in Canada, and its discovery in Montana greatly extends its known geographical and geological range. The species was not before represented in the National Museum collections.

Less perfect skeletons of carnivorous and armored dinosaurs, turtles, crocodiles, and ganoid fishes were also obtained. Altogether the material is a most welcome addition to the fossil vertebrate collection in the National Museum, which has been deficient in representatives of this highly interesting but little known fauna.

#### LIFE ZONES IN THE ALPS

During the summer of 1904, Messrs. G. S. Miller, Jr. and Leonhard Stejneger, of the National Museum, visited the Western Alps in an endeavor to ascertain the limits of the life zones which, in that part of Europe, might correspond to those of North America established chiefly through the efforts of the U. S. Biological Survey. That a system of such life zones exists in Europe has long been more or less vaguely stated by authors, but although a definite correlation was established by the gentlemen mentioned, certain points, especially the interrelation of the zones corresponding to the so-called Canadian and Hudsonian life zones in America, were greatly obscured by the long continued interference of man and animals with Nature, such as the grazing of cattle in the high Alps, deforestation, and, more recently, artificial reforestation.

It was thought that the eastern Alps might show more primitive conditions, and in the spring of 1913, Mr. Stejneger took advantage of an opportunity to visit the mountain region between Switzerland and the head of the Adriatic, through a small grant from the Smithsonian Institution. Unseasonable and rainy weather interfered greatly with the carrying out of his investigation. He arrived in the town of Bassano at the foot of the Venetian Alps on April 20, 1913, it being his plan to study the life zones of the Val Sugana and the plateau of the Sette Comuni from that point. This plateau descends abruptly to the Venetian plain on the south, while to the east and north it is separated from the mass of the Eastern Alps by the Val Sugana, or the valley of the river Brenta, and on the west by the lower part of the valley of the Adige, or Etsch. It is intersected by the boundary line between Italy and Austrian Tirol.

From April 21 to May 6, he made a series of excursions from Bassano, Levico, and Trento as successive headquarters, during

FIG. 23.—Mouth of Val Frenzela, at Valstagna, northern Italy.  
Photograph by Stejneger.

FIG. 24.—Plateau of the Sette Comuni, northern Italy, looking east from Gallio. Monte Grappa in the background. The valley is the beginning of Val Frenzela. Photograph by Stejneger.

which time he completely circled the territory, and crossed the plateau once on foot. In spite of the backwardness of the season, he was able to trace the boundaries of the Austral life zones in considerable detail, as well as to gather data which connect with the previous correlation of these zones in the Western Alps and with the corresponding zones in North America. It was found that the bottom of the entire Val Sugana belongs to the Upper Austral zone. Owing to the rainy and inclement weather the results were less satisfactory in the higher regions, though some important data corroborating previous conclusions were obtained.

The time from May 7 to May 20 was spent in a study of the Etsch Valley in Tirol, from Trento to Schlanders, and of its tributary, the Eisak, from Bozen to its source on the Brenner Pass.

The elaboration of the detailed observations will be incorporated with a general report on the biological reconnaissance of the Western Alps.

To this preliminary statement are appended two illustrations showing the character of the country in which the observations were made. Figure 23 is a view of the mouth of Val Frenzela, the narrow valley through which the descent from the Sette Comuni was effected, near Valstagna, a small town a few miles north of Bassano. Figure 24 represents the plateau near the commune of Gallio, about 3,500 feet above the sea, looking east toward Monte Grappa and showing the beginning of Val Frenzela.

#### DR. ABBOTT'S EXPEDITION IN DUTCH EAST BORNEO AND CASHMERE

In continuation of the exploring and collecting carried on through the generosity of Dr. W. L. Abbott, by Mr. H. C. Raven, in Dutch East Borneo, it may be said that the work is going forward with excellent results.

Dr. W. L. Abbott is continuing his personal explorations in Cashmere, which he undertook a year ago, and, although the Museum has received no detailed report, some fine specimens of mammals have been added to the collections and many more are expected.

In a letter received in January, 1913, Dr. Abbott says that in his last shipment the only really good specimen is a queer little silvery grey shrew about 74 millimeters long, quite different from anything he has before seen, of which there are four specimens from Skoro Loomba, east of Shigar. There is also a magnificent snow leopard with its complete skeleton.

FIG. 25.—View from Leh, looking toward the Khardery Pass up the valley to the right. Observe the cultivation in terraces, all irrigated. The elevation is 11,200 feet. The hills in the background are from 20,000 to 21,000 feet elevation. Photograph from Abbott.

FIG. 26.—Shepherds with load-carrying sheep. Each animal carries from 12 to 30 pounds. They bring salt from Tibet to Ladak and carry back grain. Photograph from Abbott.

During the three months' trip which Dr. Abbott spent in Baltistan, in northwestern Cashmere, he secured about 280 skins which have been presented to the National Museum.

After a sojourn in England, he expected to return to Cashmere in May, and march to Ladak. He also intended to visit Nubra, and go east along the frontier to the Dipsang Plains where he hoped to secure specimens of a certain vole from Kara Korum Pass, as well as the little Tibetan fox, known to the Cashmere furriers as the "King Fox." At the time of the letter he anticipated a four months' trip during the summer of 1913.

This expedition, the results of which have been delayed in transit, was very successful. The small fox was obtained, also several wolves, lynxes, and many smaller mammals. The accompanying illustrations have been made from photographs sent by Dr. Abbott.

#### MARINE INVERTEBRATES FROM THE "EASTERN SHORE," VA.

In July, 1913, Mr. John B. Henderson, Jr., a regent of the Smithsonian Institution, and Dr. Paul Bartsch, of the National Museum, made a short trip to Chincoteague, on the Atlantic shore of Accomac County, Va., for the purpose of securing exhibition material of marine invertebrates and ascertaining the local marine fauna, particularly that of the mollusca. Owing to the inaccessibility of this strip of coast, generally known as the "Eastern Shore," collectors seem to have neglected it. At any event, there appear to be but few records and no critical lists published of the shallow water shells from any locality between Cape May, N. J., and Beaufort, N. C.

The chief objects of this trip were to determine of just what elements the molluscan fauna consisted; to see how many, if any, species of southern range lapped over from Hatteras, and what northern species still persisted in this faunal area. The collectors were fortunate in their somewhat haphazard choice of a locality, for they encountered at Chincoteague a greater variety of stations than can probably be found at any other point along this section of the coast.

Here there are interior sounds of very considerable extent which are very shallow (4 to 12 ft.), more or less thickly sown with oyster beds and with patches of eel grass, the bottom ranging from hard sand, through varying degrees of hard clay, to soft mud.

They found also the unusual feature of a bight or protected cove formed by the southward drift at the southern end of Assateague Island, protected from heavy wave action by a long, curved sand spit. This bight has a soft mud bottom, with a temperature possibly

FIG. 27.— Medusa from Chincoteague, Virginia. Collected by Mr. Henderson and Dr. Bartsch. Photographed in alcohol by National Museum.

eight degrees less than that of the open sea. The mud brought up with the dredge seemed almost icy to the touch. This condition is probably produced by cold springs seeping through the floor of the bight. This colder water of the bight yielded to their dredge *Yoldia limatula*, large and fine, and *Nucula proxima*, whereas just around the protective spit of sand, on the ocean side, they found dead *Terebras* of two species, some young *Busycon perversa* and a valve of *Cardium robustum*; a somewhat startling association of species.

Then there was the open sea, which here presumably differs in no manner from other open sea stations along the 200 miles or more of this coast. The bottom drops off very gradually to the edge of the continental shelf, some 75 or 100 miles out. The open sea stations which they occupied were, as might be expected, very poor. The smooth, hard sand bottom seemed almost barren of life, and the softer patches that were explored contained only many dead shells, mostly small bivalves. The work in the open sea was scarcely a good test, although the collectors made probably 20 hauls reaching out from the shore some 4 or 5 miles, but the chart soundings indicated more promising areas of pebbly bottom a few miles beyond what they considered the safety zone for a small motor boat.

The inner waters of the sound were found to be unexpectedly rich in molluscan life, the species, for the most part, not having been taken previously outside or in the bight.

Only two full working days were spent here, where the party was fortunate in securing an excellent boat and obliging skipper. The material has been identified with great care, and the results of the expedition will be published in the Proceedings of the U. S. National Museum.

#### EXPERIMENTS WITH CERIONS IN THE FLORIDA KEYS

In the second issue of the Smithsonian exploration pamphlet,<sup>1</sup> attention was called to experiments with Cerions, conducted by Dr. Bartsch, under the auspices of the Carnegie Institution. The plantings of Bahama Cerions made upon the Florida Keys were visited in the latter part of April and early June by Dr. Bartsch, and a de-

---

<sup>1</sup> Smithsonian Misc. Coll., Vol. 66, No. 30, 1913, pp. 58-62.

tailed report of his findings is published in the annual report of the Director of the Department of Marine Biology of the Carnegie Institution of Washington (Carnegie Year Book, 1913, pp. 217-219). The results of these experiments so far obtained may be summed up as follows:

FIG. 28. — "Peanut" shells on living vegetation, Key West, Florida.  
Photograph by Bartsch.

After looking over the entire plantings, Dr. Bartsch is inclined to believe that, with the exception of the Tea Table and Indian Keys, the colonies are doing as well as might be expected. It is also quite possible that when the young in the various colonies attain a larger size, a good many more will be found in the various places, in fact,

a good many may be present in places where they were not discovered previously, for the nepionic shells are quite small and hard to find.

Judging from the young collected, which were born on these Keys, the first generation will be like the parent generation unless decided

FIG. 20.—“ Peanut ” shells on living vegetation, Key West, Florida.  
Photograph by Bartsch.

changes should take place in the later whorls, which have not as yet been developed. The largest specimens found have only seven post-nuclear whorls, leaving two to three whorls still to be developed, and these make up fully half of the length of the shell. If the present

FIG. 30.—“Peanut” shells on dead stump, Key West, Florida.  
Photograph by Bartsch.

tendencies prevail in the adult shell, then it can be seen that the somaplasm has not at once responded to the change of environment. The reaction of the germ-plasm to the changed environment will await interpretation until the next generation presents itself.

Dr. Bartsch likewise kept a record of the birds seen on the various Keys visited between Miami, Florida, and the Tortugas, and has published this also in the *Carnegie Year Book* for 1913, pp. 220-222, with the hope that it may prove useful to students of bird migration.

FIG. 31.—Detail view of "Peanut" shells on dead stump, Key West, Florida. Photograph by Bartsch.

#### BIRD STUDIES IN ILLINOIS

Mr. Robert Ridgway, curator of the division of birds, U. S. National Museum, has been working on the completion of National Museum Bulletin No. 50, *Birds of North and Middle America*, and has done some exploration work in the field in connection with this work.

Recently he made a trip to the Little Wabash River, about 16 miles southwest of Olney, Illinois, in order to ascertain what species of birds were wintering in the dense thickets of the bottom lands, and to obtain evidence as to the presence there of a decided element of the Austroriparian or Lower Austral fauna and flora.

Mr. Ridgway's residence in this locality during the winter has been of extreme interest; it is the first time he has had an opportunity to make natural history observations since his first trip to this region forty-seven years ago. He was thus enabled to compare present conditions with those existing on the occasion of his first visit, and has secured some valuable information for incorporation in his exhaustive monograph.

#### FISHES FROM THE REGION OF QUATERNARY LAKE LAHONTAN

The Museum has received through the Bureau of Fisheries a collection of fishes from the various river and lake basins that were

FIG. 32.—A breakfast catch of Tahoe Trout.  
Photograph by Snyder.

at one time connected with the quaternary Lake Lahontan. Twenty-one species are represented, 15 of which are native fishes, including not only all that are now known to inhabit the basin, but also 5 that are as yet undescribed. The collection was made by John O. Snyder, of Stanford University, while engaged in an investigation of the region under the direction of the Bureau of Fisheries.

Lake Lahontan, which in quaternary time was a large body of water, very irregular in shape, extended over a considerable part of

FIG. 33.—Mountain meadow in the high Sierra, one of the sources of the Truckee River. Photograph by Snyder.

FIG. 34.—Truckee River, outlet of Lake Tahoe, California. Photograph by Snyder.

the region now included in northern Nevada and eastern California. It was no doubt a magnificent lake, including as it did a number of large and beautiful islands, with the great snow-capped wall of the Sierra on one side and the endless shimmering desert on the other. Even now, though dwindled and shrunk through desiccation, its glory has not all departed. For although one may travel for days over the wind-driven sands of its parched floor, the great terraces and castellated crags of its ancient shores tower at times hundreds of feet on either side, and there still remain a number of small though

FIG. 35.—Humboldt River near the Palisades, Nevada.  
Photograph by Snyder.

very beautiful lakes and several rivers of considerable size which were once tributaries of the greater lake. The waters of none of these reach the ocean but ultimately disappear through evaporation, or sink into the loose, dry sands of the desert.

Lake Tahoe, near the crest of the Sierras, 6,247 feet above the sea, has 195 square miles of clear water which reaches a depth of 1,645 feet. Its outlet, the Truckee River, plunges down 2,300 feet in a distance of about 100 miles, finally bifurcating and entering Pyramid and Winnemucca Lakes. The former is 30 miles long and 12 wide, the water having a depth of over 350 feet. It embraces some pictur-

esque islands, two of which should be permanently reserved by the Government, for they shelter thousands of birds during the nesting

FIG. 36.—The Needles, Pyramid Lake. Photograph by Paine.

FIG. 37.—Tufa domes, Pyramid Lake. Photograph by Paine.

season. Humboldt, Quinn, Walker, and Carson Rivers, and also Honey, Walker, and Carson Lakes are parts of this system.

These rivers and lakes are well supplied with fishes, exceedingly abundant in number, although representing but a few species. Of chief interest and value among these are the trout which appear to have found here the most advantageous conditions for growth and development. At least 2 native species occur, *Salmo henshawi*, the large cut-throat which occasionally reaches a weight of over 20 lbs., and *S. regalis*, the royal silver trout, much smaller than the former, but a most beautiful fish, remarkable for the brilliant silver of its sides and the unparalleled blue of its dorsal surface. Formerly the lakes and rivers of the region fairly swarmed with trout, and during the spawning season they often entered the rivers in such numbers that it was difficult for them to find room in the channels. Several species of suckers and large minnows occur in countless numbers.

FIG. 38.—Bird Island, Pyramid Lake. Photograph by Paine.

Of these *Chasmistes cujus*, the Kouiewee of the Piute Indians, inhabits only Pyramid and Winnemucca Lakes. It lives in their depths, and is never seen until in the spring, when great schools suddenly appear at the mouth of the Truckee River, crowd up the channel and cover the bars, often pushing each other out of the water in their struggles to find room enough to deposit their eggs. Formerly this was an occasion of rejoicing among the Indians, for here were numbers of large, fat fishes which only need be kicked out of the water and hung on the bushes to dry. The Piutes still continue to cure them in large quantities for winter food. A small white fish abounds in favorable places. Some of the minnows reach a foot in length, bite

a fly or small spoon, and occasionally contribute to the camper's breakfast.

A study of the fish fauna of the basin bears out the conclusions of geologists regarding its long isolation. Nearly all of the species are distinct from those of neighboring systems, and some belong to groups of very restricted distribution. An account of the fishes, their habits and distribution will appear in a future bulletin of the Bureau of Fisheries.

#### CACTUSES AND DESERT PLANTS FROM THE WEST INDIES AND SOUTHWESTERN UNITED STATES

Dr. J. N. Rose, associate in botany, U. S. National Museum (at present connected with the Carnegie Institution of Washington

FIG. 30.—St. John's Harbour, British West Indies. The high point on the right is Rat Island, used as the Government Leper Asylum. Part of the town of St. John's is shown, the seat of government of the Leeward Islands under British control. Photograph by Russell.

in the preparation of a monograph of the Cactaceae of America), accompanied by Messrs. William R. Fitch and Paul G. Russell, spent over ten weeks in travel and field-work in the West Indies in the spring of 1913. As this was an unusual opportunity to obtain very valuable material needed for the collections of the National Museum and for use in making exchanges, the Museum detailed Mr. Russell

for the trip. This expedition formed a part of the larger scheme of studying in the field the desert plants of both North and South America, which had been organized by Dr. N. L. Britton, Director of the New York Botanical Garden, and Doctor Rose, in connection

FIG. 40.—A *Cereus* (*C. lepidotus* Salm-Dyck) common on these islands. Near St. John's, Antigua. Photograph by Russell.

with their Cactus Investigation for the Carnegie Institution of Washington. Doctor Britton also took a party to the West Indies.

Both parties started from New York City January 25. Doctor Britton and his assistants explored St. Thomas, St. Jan and others of the Virgin Islands, Porto Rico, and Curacao. His collection consisted of more than 3,000 species, comprising two sets, one of which has been sent to the National Museum as an exchange.

FIG. 41.—A specimen of the Century plant (*Agave obducta* Trelease) showing an immature flowering stalk. Near English Harbour, Antigua. Photograph by Russell.

FIG. 42.—Specimens of the Melon-cactus (*Cactus intortus* Mill.) and Century plant (*Agave obducta* Trelease) on promontory near English Harbour, Antigua. English Harbour was once a fortified British stronghold. Admiral Nelson here fitted up part of his fleet for the Battle of Trafalgar. Photograph by Russell.

At the same time, Doctor Rose's party visited St. Thomas, St. Croix, St. Kitts, Antigua, and Santo Domingo. Knowing that the Museum greatly needed duplicates for exchange purposes, general collecting was done whenever possible. Dr. Rose's collection consisted of more than 1,200 species and about 7,000 specimens. Of these, one set has been mounted for the Museum and has become a part of the study series of the herbarium. A second set was sent to the New York Botanical Garden, while other sets have been sent to the Bureau of Science at Manila, and to the Royal Botanical Garden and Museum at Berlin, for use by Dr. I. Urban in the preparation of his Flora of Santo Domingo.

While especial attention was given to collecting the Cactus flora, a large general botanical collection was made. In this there are some new species, one in particular being a very remarkable *Ammonia* from the desert plain at Azua, Santo Domingo.

In addition to the herbarium material, 12 boxes and crates of living plants, chiefly Cacti, were sent from the West Indies by Doctor Rose, and two boxes of living plants were sent to Lady Katharine A. Hanbury's garden at La Mortola, Italy, in exchange for specimens and courtesies shown to Doctor Rose when in Europe in 1912.

Many packages of seeds, bulbs, cuttings, etc., were obtained for exchange purposes of the Museum or for study by the various workers in the U. S. Department of Agriculture.

#### PLANTS FROM SOUTHWESTERN UNITED STATES

In September and October, Doctor Rose, accompanied by Wm. R. Fitch, made extensive botanical collections in southeastern Colorado, New Mexico, and western and southern Texas. While the trip was made primarily for the purpose of collecting and studying the Cacti of this region, many other flowering plants were obtained, a full set of which has been mounted and placed in the National Herbarium.

#### THE FLORA OF WESTERN NORTH CAROLINA

During the latter part of August and early September, 1913, Mr. Paul C. Standley, of the Division of Plants, U. S. National Museum, and Mr. H. C. Bollman, of the Smithsonian Institution, spent four weeks camping in the mountains of western North Carolina, near Montreat, Buncombe County. Although undertaken primarily as a vacation trip, advantage was taken of the opportunity for study of the flora of this most interesting region. Over seven hundred speci-

mens of plants were secured, besides small lots of some of the common and easily collected animals. Special attention was devoted to the mosses, hepatics, and lichens, in which the region abounds, and a representative collection of each of these groups was secured. Lists of the species of cryptogams have been prepared for publication.

FIG. 43.—Mountain brook near Montreat, North Carolina. Photograph by Standley.

The mountains of North Carolina are of great interest botanically, since they support a varied flora, many of whose components are not found elsewhere. Western North Carolina was visited by some of the earliest American botanists who collected here the types of many of the typically mountain plants. Although numerous botanists have explored the region, many of its divisions are still unexplored and yield rich returns to the collector.

About Montreat the mountains are covered with an almost virgin chestnut forest, traversed by numerous small, swift streams of clear, cold water, bordered with hemlocks. There is an abundant undergrowth of rhododendron and laurel, two of the handsomest of North American shrubs, which attain their greatest perfection in the southern Appalachians. The herbaceous vegetation consists of many

FIG. 44.—Chestnut forest near Montreat, North Carolina. Photograph by Standley.

species, some of them of limited distribution. A small sphagnum bog, in particular, yielded a large number of rare plants.

The most interesting excursion made during the month's camp was to the summit of Mount Mitchell, the highest peak in eastern North America—6,710 feet. By trail, it is distant about sixteen miles from Montreat. The trail at first follows a logging railroad which is being extended into the mountains, then strikes through the heavy

spruce and balsam forest covering the higher slopes. This primeval forest, which resembles in its general appearance those of the Rocky Mountains, unfortunately seems destined to disappear in the near future; indeed, it has already been removed from a large area, and desolation left in its stead. It is deeply to be regretted that as Mount Mitchell is made more accessible by the railroad its chief beauty will be destroyed.

A single night was spent on the summit of the mountain. A cabin was built here and maintained by the State some years ago, but it is now abandoned and has fallen into decay. At the summit of Mount

FIG. 45.—Artificial fountain near Black Mountain, North Carolina. It is fed from a reservoir on a neighboring mountain. Photograph by Standley.

Mitchell is a monument which marks the grave of the man whose name it bears, who lost his life while engaged in exploring its slopes. From this point at sunrise a wonderful view is obtained of the vast mass of mountains which cover the adjacent region, their valleys filled with a sea of clouds above which the higher peaks rise like rugged islands.

A small collection of plants was made upon the peak, a locality whose flora is little known. The flora, strangely enough, is not particularly interesting, for it includes but few species. The vegetation is remarkable chiefly for the large number of introduced plants it includes. These have doubtless been transported by the visitors who ascend the mountain each year. In spite of the altitude of Mount

Mitchell, it yields none of the boreal plants which make the floras of the mountains of New England so interesting. The lower mountains of North Carolina, and some of the other high peaks, are much more interesting botanically than this, the loftiest of them all.

#### ANCIENT MICA MINES OF NORTH CAROLINA

In April, 1913, W. H. Holmes, head curator of the department of anthropology, visited the mica mines of western North Carolina, making such observations as seemed necessary for a reasonable comprehension of the nature and extent of the ancient operations.

FIG. 40.—Section of an aboriginal mica mine: *A*, General schistose formation; *B*, Mica-bearing vein; *C*, Old digging partly filled up; *D*, Ancient dumps.

Mica was in very general use among the Indian tribes east of the Great Plains and was mined by them at many points in the Appalachian highlands from Georgia to the St. Lawrence River. From these sources it passed by trade or otherwise to remote parts of the country and is found especially in burial mounds, stone graves, and ordinary burials throughout the Mississippi Valley. The crystals of mica are of diversified shapes and sizes, reaching in some cases upwards of two feet in dimensions. They separate readily into sheets of very attractive appearance, which are transparent or translucent, displaying various silvery and amber hues. Mica crystals occur distributed through narrow veins of quartz and feldspar which extend at various angles through the inclosing schistose formations.

Although probably serving few practical purposes the sheets were highly prized by the aborigines for the manufacture of personal or-

naments and for sacrificial and mortuary purposes. It is stated on good authority also that they were used as mirrors.

Mr. Holmes visited a number of mines in the vicinity of Spruce-tree and Bandana, Yancey County, and near Bakersville in Mitchell County. The most important workings in the first mentioned locality are known as the Sink Hole mines, near Bandana. Although these mines have been operated extensively in recent years, sufficient traces of the old work remain to convey a fair notion of the nature and extent of the prehistoric mining. There are two main groups of pittings, each approximately 1,000 feet in length and 20 to 60 feet in

FIG. 47.—Stone picks used in excavating and freeing the crystals of Mica.

width. The original depth in many cases was upwards of 40 feet, but recent operations of white miners have served to change their appearance, and to fill up the deeper excavations. The pittings are surrounded by a somewhat uneven ridge of detritus derived from the excavations, which has been added to in places by the modern miners, and has been dug into of late years to recover the mica rejected and thrown out by the aborigines.

An important site of the ancient operations now known as the Clarissa mine, three miles east of Bakersville, Mitchell County, was also visited. This is probably the best preserved and most striking of the aboriginal workings in this general region, and serves to illustrate the importance of the mica industry in prehistoric times. Entering a

low ridge at an oblique angle, the excavation reaches a depth of nearly 100 feet. The outer margin is buried beneath heavy bodies of ancient dump material which now supports numerous chestnut trees, the trunks of which are four or five feet in diameter. The modern operators of the mine who have worked the vein at the upper end to the depth of 300 feet have filled the old trenches deserted by the aborigines.

So far as could be determined, the implements used in excavating the decomposed schists and breaking up the vein material, thus freeing the mica crystals, were rude picks and hammers of stone, a few examples of which were found. Drawings of these are shown in figure 47.

Mr. Holmes extended his reconnoissance into South Carolina, where an ancient mound of large dimensions, situated twelve miles below Columbia on the Congaree River, was examined. A plan of the mound was made, and an examination of an ancient burial site on the edge of the mound yielded numerous relics of pottery and stone.

Near Waynesboro, Georgia, a number of ancient village sites and certain outcrops of flint, where the aborigines had obtained the material for their implements, were examined. Later, in the spring, Mr. Holmes visited St. Louis, Missouri, with the view of studying the very interesting collections owned in that city, and accompanied by Mr. Gerard Fowke spent a day at Mill Creek, Illinois, making collections on the ancient quarry and shop sites of that locality. He later extended his excursion to Davenport, Madison, Milwaukee, Chicago, and Columbus, for the purpose of making studies in the museums of those cities.

#### ANTHROPOLOGICAL EXPLORATION IN PERU

Dr. Aleš Hrdlička, of the National Museum, has made a second report<sup>1</sup> concerning his field-work in Peru during the past year, in connection with the Panama-California Exposition at San Diego, for which a very important exhibit in physical anthropology is being prepared. The investigations extended over several hundred miles of the Peruvian coast and over hitherto unexplored regions in the western Cordilleras. The objects of this trip, which occupied the first four months of 1913, were to determine the anthropological relations

---

<sup>1</sup> Anthropological Work in Peru in 1913, with Notes on the Pathology of the Ancient Peruvians. Smithsonian Misc. Coll., Vol. 61, No. 18, 1914.

of the ancient Peruvians of the mountains with those of the coast, and to extend the investigations which Dr. Hrdlička has carried on for many years, regarding Indian and especially pre-Columbian pathology.

The expedition was a very strenuous one, but proved remarkably successful. Over 100 ancient cemeteries and many ruins, a large

FIG. 48.—The picturesque town of Huarochiri, in the western Cordillera of central Peru. Photograph by Hrdlička.

percentage of which were previously unknown to science, were examined and over 30 boxes of skulls and other material for future study were collected for the U. S. National Museum and the Museum at San Diego.

Dr. Hrdlička reports that skeletal material, which formerly abounded in Peru and is essential to scientific research, is fast disappearing, and in a few years can not be gathered without the expenditure of much time and money.

The results of the expedition will prove of unusual value to anthropology. While some of the links in the chain of evidence are still missing, it can now be said with certainty that the Peruvian coast from Chiclayo, in the north, to Yauca, in the south—a distance of over 600 miles—was peopled predominantly before the advent of the whites by one and the same physical type of Indian. These Indians were of medium height, with short and broad skulls, and

FIG. 49.—The ruins of the Incaic Temple of the Sun, at Pachacamac, Peru. Photograph by Hrdlička.

moderately to strongly developed muscles according to the locality. The most important fact ascertained in this connection was that both the Chinu and Nasca, two of the foremost cultural groups of ancient Peru, were identical and, as regards physical characteristics, inseparable parts of this coast people.

According to their location, the people of old Peru were either fishermen or farmers. They seem to have been organized into numerous political groups, which developed smaller or greater cultural differences according to environment and other influences.

FIG. 50.—Ancient cemetery in Peru; a typical example of the waste of pottery and bones by the despoiling peons. Photograph by Hrdlička.

FIG. 51.—Cache, by the explorer, of ancient pottery left behind by vandals after despoliation of a cemetery south of Huacho, Peru. Photograph by Hrdlička.

Some of their smaller dwellings were made of reeds, while larger structures were built of small uncut stones, sun-dried brick, or blocks of adobe. Their knowledge of weaving, pottery-making, and decoration was surprising. They wove from native cotton and llama wool, and their designs indicate changes brought about by time and other influences. The native dress consisted principally of a poncho shirt, a loin cloth, and sandals, with occasionally a simple head-gear.

The pre-Columbian Peruvians of the coast knew the uses of gold.

FIG. 52.—Indian hut and inhabitants, with a ruin-covered hill known at Llaxwa, in the rear, located in the Sierras, south-east of Nasca, Peru. Photograph by Hrdlička.

silver, and copper, and worked these metals to some extent, especially copper or "bronze" in the manufacture of weapons. Their common weapons were a metal or stone mace, a wooden club, a copper axe and knife, the sling, and in some regions the bow and arrow. Their implements were the whorl, weaving sticks, looms, cactus-spine or bone needle, bone needle-holders, sharpened sticks, copper knives and axes, hoes and fishing paraphernalia, including nets, sinkers, reed-bundle boats or balsas, and peculiar rafts which were paddled.

Throughout the whole territory along the coast the people deformed the heads of their infants by applying pressure to the fore-

head probably by means of pads and bandages, which process flattened the back of the head as well. They did not practice filing, cutting, or chipping the teeth, or other mutilations which would leave marks on the skeletons.

These natives seem to have been free from general bodily ailments before the advent of the white men; on the other hand they suffered from several peculiar local diseases affecting the hip-bone, the head, and the ear.

FIG. 53.—A party of vandals in an old cemetery on the railroad from Ancón to Huacho, Peru. Photograph by Hrdlička.

The people of the mountains possessed a good average development of the body and of the skull, and were even freer than the coast people from disease. Wounds were, however, common, and in some of the districts serious wounds of the head were frequently followed by the operation known as trepaning, and although this was often crudely done, it was successful in many cases. This practice was probably carried on even after the coming of the Spaniards.

The results of the expedition failed to strengthen the theories of any great antiquity of man in Peru, tending rather to prove the con-

trary. Aside from the cemeteries or burial caves of the common coast or mountain people, and their archeological remains, there was no sign of human occupation of these regions. Not a trace suggesting anything older than the well-represented pre-Columbian Indian was found anywhere; and neither the coast nor the mountain population, so far as studied, can be regarded as very ancient in the regions they inhabited. No signs indicated that any group occupied any of the sites for even as long as 20 centuries; nor does it seem that any of these people developed their culture, except in some particulars, in these places.

#### ARCHEOLOGICAL EXPLORATIONS IN WESTERN NEW MEXICO

Mr. F. W. Hodge, ethnologist-in-charge of the Bureau of American Ethnology, in the early autumn of 1913 made a reconnoissance of

FIG. 54.—Character of masonry shown in one of the house-groups of the compound. Note the failure of the builders to “break” the joints and the consequent weakening of an otherwise excellent wall. The face of the stones is pecked to smoothness and all the stones are artificially squared. Photograph by Nusbaum.

a group of ruins on a mesa rising from the southwestern margin of the Cebollita valley, about 20 miles south of Grant, Valencia County, New Mexico, and only a few yards from the great lava flow that has spread over the valley to the westward for many miles. While no very definite information regarding the origin of this ruined pueblo

FIG. 55.—Stone outer wall of a defensive structure near the mesa rim. This wall is about 132 feet long in the clear, and is pierced only by small loop-holes. Photograph by Nusbaum.

FIG. 56.—Skeleton, with burial accompaniments, found in a small cist. Photograph by Nusbaum.

FIG. 57.—View southward across Cebolllita valley, New Mexico. The lower mesa across the valley is that on the summit of which are situated the chief ruins described. Photograph by Nitsbaum.

FIG. 58.—Smaller reservoir, probably chiefly a natural depression, in the rocky floor of the mesa-top; looking southward. Photograph by Nusbaum.

has yet been obtained, there is reason to suppose that it was occupied by ancestors of the Tanyi, or Calabash, clan of the Acoma tribe, and is possibly the one known to them as Kowina.

These ruins consist of a number of house-groups forming a compound, built on an almost impregnable height, and designed for de-

FIG. 59.—Small cliff-house on the northern side of Cebollita valley. Photograph by Nusbaum.

fence; not only the groups but the individual houses have the form of fortifications, while the vulnerable point of the mesa rim is protected by means of a rude breastwork of stones.

The outer wall, which protects the whole mesa, is built of exceptionally fine masonry, probably the finest work to be found in ancient

pueblo ruins of the Southwest. The building stones have been dressed to shape, matched for size, and their faces finished by pecking, with such labor as to confirm the belief that this ancient village was designed for permanent occupancy. Altogether the work proves of great interest, and it is surprising to note the one failing, on the part of these early builders: they seem to have been unaware of the necessity of breaking the vertical joints in the courses of masonry, thus causing many weak points in the otherwise excellent walls.

Among the special features of interest which Mr. Hodge discovered were a burial cist where skeletons, pottery, and the remains of a mat were found; three small cliff lodges situated in the sides of the cliffs; several ceremonial rooms or kivas associated with the ruined houses, and the remains of the early reservoirs of the inhabitants.

A full report on the exploration of this interesting pueblo will be made by Mr. Hodge in a later publication.

#### ANTIQUITIES OF THE WEST INDIES

Dr. J. Walter Fewkes, ethnologist in the Bureau of American Ethnology, spent January, February, March, and part of April, 1913, in the West Indies, studying the prehistoric antiquities of the Lesser Antilles, and gathering material for a proposed monograph on the aborigines of these islands. He examined numerous local collections, and visited many village sites, prehistoric mounds, shellheaps, and boulders bearing incised pictographs.

The most extensive excavations during these months were made at Erin Bay, Trinidad, in a shellheap of considerable size, where he found a valuable collection of animal heads made of terra cotta and stone, and other objects illustrating the early culture of that island. From Trinidad he went to Barbados, where he found evidences of the former existence of cave people living in a shell age or one in which stone was replaced by shell. Excavations were later made at a village site of the Black Caribs at Banana Bay, Balliceaux, a small island near St. Vincent, and a small collection was gathered from it.

He obtained many drawings of specimens in a rich collection from St. Kitts and Nevis, owned by Mr. Connell, and examined the shellheaps at Salt River, Christianstadt, St. Croix, and at Indian River, Barbados. The collection of prehistoric objects obtained from St. Croix, Danish West Indies, was ample to prove that the early culture of the inhabitants of this island was more closely related to the culture

of Porto Rico than to that of St. Vincent. The material obtained in this field-work will be embodied in a report which Dr. Fewkes has in preparation on the magnificent collection of West Indian prehistoric objects owned by George G. Heye, Esq., of New York. The exploration was done in coöperation with the Heye Museum.

Field-work in the West Indian islands was supplemented by a visit to those museums in Europe where extensive Antillean collections exist. August, September, and October were devoted to studying prehistoric West Indian objects in Berlin, Bremen, Copenhagen, Vienna, and Leipzig. While in the first mentioned city he employed Mr. W. von den Steinen to make drawings of the originals of the Guesde Collection and many other objects from Hayti, Porto Rico, and the Lesser Antilles.

In the Bremen Museum a stone collar was found to have its knob modified into a reptilean head, an unique feature that would seem to shed light on the meaning of these objects. The Museum at Copenhagen has a rare ceremonial celt connecting petaloid stone axes with stone heads.

These field-studies and examinations of museum specimens have led Dr. Fewkes to the conclusion that in prehistoric times there existed in the Antilles a race of sedentary people having a form of culture extending from Trinidad to Porto Rico. This culture differed in minor details, in the various islands, as the style of stone implements, pottery, and other objects of material culture in all these islands shows. It was preceded by a life in caves which survived in western Cuba and the western peninsula of Hayti down to the time of the discovery by Columbus. The Caribs, who came comparatively late, brought a different culture that overlaid and, in a measure, absorbed the preceding culture in the Lesser Antilles. In other words, evidences were found of at least three distinct types of culture in the Lesser Antilles: cave, agricultural, and Carib. The second or agricultural type was found to have the subdivisions localized in the following groups of islands: Cuba, Santo Domingo, and Porto Rico; St. Kitts, including Nevis; the volcanic chain of islands from Guadeloupe to Grenada; Barbados; and Trinidad.

As with all other sciences, the highest form of research in culture history is comparative. It is universally conceded that the race inhabiting the New World, when discovered, had not advanced in autochthonous development beyond the neolithic age, whereas in Asia, Europe, and Africa a neolithic age was supplemented by one in which metals had replaced stone for implements. In the Old World

this polished stone epoch had been preceded by a paleolithic stone age not represented, so far as is known, in America. The ethnology and archeology of our Indians therefore form only a chapter, and that a brief one, or a segment of a much more extended racial evolution, as illustrated in Asia, Europe, and Africa.

It is profitable to compare the neolithic stone ages in the New World and the Old in order to appreciate rightly the position of the American Indian in the advance of human history, and his relation to the dawn of human history.

In order to carry on comparative studies of the stone age of aboriginal America and the corresponding age in the Old World, Dr. Fewkes spent six months in field and museum work in Europe and Africa. He visited the prehistoric mounds, dolmens, and megalithic monuments at Stendal and Stöckheim in Altmark, a short distance from Berlin, and examined the finely installed collections from these localities in local museums. He also visited the island of Rügen, in the North Sea, where there are many prehistoric mounds, Huns' graves, workshops, and megalithic and other remains of the neolithic inhabitants. The many antiquities from this island in the museum at Stralsund furnished considerable data for a comparative study of artifacts from this part of Europe with similar objects from North America.

Dr. Fewkes believes that the time is past when the great ruins in our Southwest should be left to destruction by the elements, after smaller objects have been extracted from them. In order to protect these ruins he has inaugurated, under the direction of the Smithsonian Institution, at Casa Grande, Spruce-tree House, and Cliff Palace, a scientific method of excavation and repair. In order to improve his methods by becoming better acquainted with excavation and repair work adopted by the ablest European archeologists, he visited Egypt, Greece, and Italy (Pompeii).

He found in some cases that whereas repair work in the Old World is often neglected and cannot be called very scientific, and some of the excavated ruins have been left in very bad condition for future students, the majority are being carefully protected after excavation, in a manner well worth study by those who aspire to the most advanced standards.

The best archeological repair work in Egypt may be seen on the Temple of Amen Ra at Karnak, and the mortuary temples, the Ramesseum, Medinet-Habu, and the Seteum, from which were obtained valuable suggestions. The admirable repair of the hypo-style

hall of the Temple of Amen Ra, by M. Le Grain, is the most important ever attempted on an ancient building.

Part of his time in Egypt was devoted to comparative problems, and he was also able to give some attention, all too limited, to evidences of convergence and parallelism in the neolithic or predynastic culture of the Nile Valley with that of the Gila. He investigated more especially remarkable lines of similarity in artificial methods of water supply, in both regions, and the influence of coöperation of predynastic villages in building great irrigation canals, on the development of a higher social organization. He had always in mind the collection of material bearing on interrelationship of climatic conditions and early culture in the Nile Valley.

#### AMONG THE EAST CHEROKEE INDIANS OF NORTH CAROLINA

Mr. James Mooney, ethnologist in the Bureau of American Ethnology, spent the summer of 1913, June 18 to October 4, inclusive, with the East Cherokee Indians in the mountains of western North Carolina, among whom he had made his first field studies in 1887. These Indians, numbering some 1,000, live upon a small reservation in Swain and Jackson Counties with several outlying settlements farther to the west. They are a part of the historic Cherokee Nation formerly holding the whole mountain region of the southern Alleghenies until removed by military force in 1838 to the Indian Territory, where they now number about 30,000 of pure or mixed blood. Those in North Carolina are the descendants of some hundreds who made their escape from the troops and were finally, through the good offices of their friend, Col. Wm. H. Thomas, allowed to remain and settle upon lands purchased for them with their share of the fund originally appropriated for their removal to the west. There are still living among them several who remember the removal.

Constituting from the beginning the most conservative and pure-blooded element of the tribe, protected by their mountain barriers from outside influences and never having been subjected to the shock of forced removal to a distant and strange environment, these East Cherokees remain to-day the conservators of the ancient traditions, and exemplars of the aboriginal life once common in varying degree to all the tribes of the Gulf States. Until 1881, when the first school was established, they continued virtually unchanged. Since then, schools, railroads, and lumber industries have made rapid advance, which, with the passing of the older generation, must before many years bring to a close the Indian period.

On this occasion, Mr. Mooney made headquarters in the largest and most conservative settlement, locally known as Raven Town or Big Cove, some 12 miles from the agency, over a very rough mountain road impassable for vehicles during a part of the year. Here, shut in by the highest peaks east of the Mississippi, some 500 Indians dwell in fairly comfortable two-room log cabins perched high up on

FIG. 60.—Cherokee potter; Katalsta, daughter of Yanagūski, "Drowning Bear," Head chief of the East Cherokee about 1838. Photograph by Mooney.

the slopes of the mountains, always near a convenient spring. They till their fields of corn and beans, which extend sometimes even up to the crest of the ridge. Some have oxen, and a few have horses, but the great majority cultivate their fields by hand, and travel always on foot.

While many are nominally Christians, and most of the younger people can speak English, they still, as a community, adhere to their

ancient rites of the Green Corn dance, the "going to water" at every new moon, the fishing and hunting charms, the medicine man, and the native ball game. Many of the women are expert in basket making, in a variety of patterns, but the pottery art, which flourished a few years ago, is now virtually extinct. The blow-gun, formerly used for shooting small game, is now almost a thing of the past, together with the head turban and the moccasin.

Although the outer life and semblance are thus altered, the possession of a native alphabet or syllabary, invented by a mixed blood of the tribe nearly a century ago, has enabled their priests and doctors to preserve their ancient ritual prayers and formulas without change and apparently almost without diminution from the remote past. By good fortune some twenty-five years ago Mr. Mooney was enabled to obtain some hundreds of these Cherokee manuscript formulas, the secret possession of their leading priests. Many others have been obtained on later visits, in addition to much miscellaneous ethnologic material, until the collection now numbers approximately 600 formulas, perhaps the equivalent of as many printed quarto pages, covering every occasion of Indian life, war, love, hunting, fishing, agriculture, medicine, games and ceremonials. This collection of aboriginal American literature is unique and without parallel. As a revelation of primitive psychology it is invaluable. The antiquity of the formulas is sufficiently indicated by the abundance of archaic forms and references, many of which cannot now be explained even by the priests, who simply say, "This is the way it was given to us." Many of these formulas are highly poetic.

The explanation of those originally obtained, almost one-half the whole collection, was procured from the principal recognized priests of that time, all of whom are now dead. At the same time, all the words of the formulas were glossarized, and all the plants mentioned in the medical prescriptions collected, and labeled with their Indian names, and later identified botanically by experts of the Smithsonian Institution. Other formulas have been translated and explained during subsequent visits. During the last summer the number was considerably enlarged by the best known teachers. All those then untranslated were translated and glossarized, and the additional plants named therein collected. The whole body was then revised from the beginning, so that nearly every formula has now had the interpretation of at least three recognized authorities. There is still a paucity in certain classes as compared with others, notably in the formulas relating to war and to the ball play, as compared with those relating

to medicine and love. This deficiency may be supplied by future gatherings, but for the formulas already translated, it may be confidently affirmed that no important additional light is now procurable.

While the formulas constitute the largest body of aboriginal American literature extant, the plant collection constitutes probably the largest ethno-botanic collection from any one tribe, comprising some 700 species with Cherokee names and uses, nearly all of which have been scientifically identified by expert botanists. This collection represents the combined plant knowledge of the principal doctors in the tribe.

Opportunity was also afforded for special studies and observations, particularly of the ceremonial "going to water," and augury with the beads to forecast the health prospect and life-span of each member of the family, before partaking of the first corn of the new crop.

#### CEREMONIAL DANCES OF THE CREEKS IN OKLAHOMA

In July and August, Dr. John R. Swanton of the Bureau of Ethnology visited the territory of the old Creek Nation in Oklahoma,

FIG. 61.—The "Feather" dance, Fish Pond square ground.  
Photograph by Swanton.

to attend several of the ceremonial dances or busks about which he had collected much information in previous years. He witnessed four of these ceremonials: that of the Eufaula Creeks near Eufaula, McIntosh County, those of the Hilibi and Fish Pond Creeks near Hanna, in Hughes County, and that of the Tukaba'tei near Yeager. Notes were taken on all of them and a number of photographs were obtained of the first three. Considerable supplementary information

FIG. 62.—The women's dance, Fish Pond square ground.  
Photograph by Swanton.

FIG. 63.—"Feather" dance, Hilibi square ground. Photograph by Swanton.

was secured from the older men regarding the busk ceremonial and other ancient usages.

When the ceremonies were over Dr. Swanton visited the Indians in Seminole County, who still speak Hitchiti, a language formerly current throughout southern Georgia, and recorded several texts. He also secured the cooperation of a Hitchiti Indian, able to write in the missionary alphabet, to obtain other texts after his departure.

#### CEREMONIES AND RITUALS OF THE OSAGE

During the year 1913, Mr. Francis LaFlesche of the Bureau of American Ethnology secured the songs and rituals of five different Osage ceremonies. Two of these are practically complete; the others are fragmentary, but enough information was obtained to give a fair idea as to their significance. These rites are: *Wa-dó-ka We-ko*, Scalp Ceremony; *Wa-zhiú-ga-o*, Bird Ceremony for boys; *Wa-wathon*, Peace Ceremony; *Zhiú-gá-zhiú-ga Zha-zhe Tha-dse*, Naming of a Child; and *We-xthe-xthe*, Tattooing Ceremony.

Owing to the superstitious hold these rites still have upon the people, together with the fact that every initiated person obtained his knowledge at a great expense, it was almost impossible to procure complete texts of any of the ceremonies.

The Tattooing Ceremony is of peculiar interest. It was more difficult to secure information concerning it than of any other ceremony. In earlier times only the warrior who had won war honors was entitled to have the ceremony performed and have the war symbols tattooed upon his body. If his means permitted it, they might also be placed upon any number of his relatives. These war symbols were his marks of distinction as a man of valor, for the strength and life of the tribe depended upon the prowess of the warriors. In those days there were but few who were entitled to have the ceremony performed, because war honors were not easily won and few were wealthy enough to afford the expense of the ceremonies. When, during the last century, wars between the various tribes ceased, the real significance of the rite vanished, but the superstitious belief that the symbolic figures meant long life to the individual so tattooed, remained prominently in the minds of the people.

About the time that the right of the honored warrior to the exclusive use of the Tattooing Ceremonies came to an end, a new condition arose which materially changed the character of the rite. From the sales of lands to the United States the Osage tribe acquired a wealth by which a greater number of its members were enabled to

have performed the tattooing, as well as other ceremonies. It was then that this ancient rite became the means by which any individual could publicly display his affection toward a relative.

FIG 64.—An Osage Indian with tattooing.

Figure 64 shows designs tattooed upon the body of a man. Those on a woman are more elaborate and cover the upper part of her body, breast and back, and the lower part of her legs. Figure 65 shows

three implements used in tattooing. Each of these is made of wood about the length of a pencil. To the lower end are attached needles arranged in a straight row, and to the upper end are fastened four small rattles made of the large wing quills of the pelican. This

FIG. 65.—Three implements used in Osage tattooing. Photograph by DeLancey Gill.

bird is referred to in one of the dream rituals as, *Mon-thin-the-don-ts'a-ge*, He-who-becomes-very-old-while-yet-going. In certain passages of the ritual it is intimated that these implements were originally made of the wing bone of this bird and were used for doctoring as well as for tattooing.

The coloring matter employed in tattooing is made of charcoal mixed with kettle black and water. The charcoal is made from certain trees that serve as symbols of long life in the war ceremonies. Tail feathers of the pileated woodpecker are used for putting on the ink and drawing the lines.

On November 17, 1910, Wa-cé-ton-zhin-ga, one of the prominent men of the Pa-ci-n-gthin band (Hill-top Dwellers) died. It was learned that he had a Wa-xó-be-ton-ga, a Great Wa-xó-be. This is a white pelican, the bird which is supposed to have revealed, through a dream, the mysteries of tattooing and to have supplied the implements. On February 16, 1911, Wa-cé-ton-zhin-ga's widow after much persuasion reluctantly consented to part with this sacred object (the Great Wa-xó-be), together with its buffalo hair and rush mat cases. It was thus secured by the writer, and now has a place in the United States National Museum.

#### A STUDY OF SIOUX MUSIC

The field-work of Miss Frances Densmore during the season of 1913 was concentrated on the southern portion of the Standing Rock

FIG. 66.—Indians dancing the Grass Dance at Bull Head.  
Photograph by Miss Densmore.

reservation, which lies in the State of South Dakota. Many acquaintances had been made on a previous visit to the locality, and the earlier knowledge gained of the Indians opened the way for intensive work along the lines which had been selected, *i. e.*, songs of war, songs connected with the use of medicinal herbs, and songs of tribal social

organizations. As in previous years, the songs were recorded phonographically, about 130 songs being secured in this manner for the Bureau of American Ethnology.

In connection with this work Miss Densmore collected about 120 specimens, illustrating the old arts and industries as well as the customs of war and the practice of medicine. Twenty herbs said to have medicinal properties were secured from medicine men who use them in treating the sick. These herbs were identified at the Department of Agriculture in Washington, and a number of them were found to be in use among physicians of the white race.

FIG. 67.—Indian equipment for boiling meat without a kettle. Photograph by Miss Densmore.

During the celebration of July Fourth, at Bull Head, many old dances were given. Figure 66 shows the Indians at this celebration of the Grass Dance. A demonstration of the manner of boiling meat without a kettle was also given, Miss Densmore witnessing the process and afterward purchasing the entire equipment, shown in figure 67. This was of interest in connection with the subjects under investigation, as it was a method used in old times by Indians on the war path or buffalo hunt. The paunch of a freshly killed animal was suspended between three stakes, water was placed in it, and brought to the boiling point by means of heated stones. Meat was

thoroughly cooked in this manner. A portion of the meat thus prepared was secured in connection with the apparatus.

Many of the war songs were illustrated by native drawings. Figure 68 shows a man known as Jaw, an old warrior with a wide reputation

FIG. 68.—Jaw, an old Sioux warrior, whose horse-stealing expeditions are illustrated by his own drawings in the background. Photograph by Miss Densmore.

for stealing horses. Behind him is one of his drawings depicting such an expedition.

A medicine man with his drum is shown in figure 69. This man was named White Paw Bear, and proved a valuable informant to Miss

Densmore. He was a close friend of the famous chieftain Sitting Bull.

FIG. 60. White Paw Bear, a medicine man with his drum.  
Photograph by Miss Densmore.

Miss Densmore attended a large feast given in her honor by Red Fox, the Sioux chief who adopted her two years previously in place of his daughter. This adoption was ratified later by the tribe.

## STRANGE RITES OF THE TEWA INDIANS

Mrs. M. C. Stevenson continued her comparative study among the Tewa Indians of the Rio Grande valley, in behalf of the Bureau of American Ethnology. A close relationship was found to exist among all the Pueblo Indians, especially in their essential beliefs, resulting in a great brotherhood between them. Living in an arid land the cry of their souls was and is—"rains to water the earth."

Primitive man sought to define the mysteries of Nature, to account for its phenomena; thus primitive philosophy was born, and then re-

FIG. 70.—Plaza and kiva of the Sun people, San Ildefonso. X denotes the entrance to the kiva. Photograph by Mrs. Stevenson.

ligion and ritualism crept in. The Pueblo Indian began at an early period to create a pantheon of gods of his worship, gods to be appealed to for the good things of life, and angry gods to be propitiated, and thus, long ago, a most complicated system of religion and rituals developed among such peoples of the Southwest as had homes constructed of stone, clay, and plaster.

The more clever men of the past ages differentiated their gods into two classes, anthropic, principally ancestral, and zoöic, and these men assumed to dominate the remainder of the people by asserting their direct communication with the gods. Through their power and influence with these gods they were next in importance to the gods them-

selves. Their doctrines taught that: The gods who bring good are exacting, and man must comply with the demands of his gods in order that the godly blessings may be bestowed upon him. He must not only perform the religious duties assigned him, but observe proper intelligence in the performance of these rites. "In the far past Avä<sup>m</sup>nyu, the great plumed serpent, whose home is in the depths of the lake of the departed, determined to take a journey over the upper plane so that he could look below and observe the people of this world.

FIG. 71.—Circular kiva at Pueblo of Nambe, New Mexico.  
Photograph by Vroman.

Upon viewing a certain village on the summit of a mesa not many miles from the present pueblo of San Ildefonso on the Rio Grande, he discovered that though the people were devout, their rituals were all wrong and as a punishment for their ignorance he converted them into *sí'de* (small bird), Mexican pajarito, and had them fly away. Since that time the deserted village has been called Sí'de ge, small bird place. These ruins are known to the outside world as the Pajarito ruins.

Religion and ritual kept pace with the development of man. The peoples more remote from the long-continued influence of Roman

Catholic priests, retain more of their elaborate rituals and native paraphernalia than those who have been under the control of the Church.

FIG. 72.—Rain priest of Sun people of Nambe. Photograph by Mrs. Stevenson.

Priesthoods and fraternities were organized, and chambers were built in which to invoke and propitiate the gods. These chambers were circular and built under ground, symbolizing the innermost world

whence the people came. As the people ascended from these chambers, they symbolized their emergence from the innermost world

FIG. 73.—Juan Gonzales, associate rain priest, and present governor of San Ildefonso. Photograph by Mrs. Stevenson.

into this world; and, although most of the kivas, or Hopi ceremonial chambers, at the present time, are above ground or partially so, they

still represent the undermost world, the coming out still symbolizing the emergence from the undermost world, and the kiva the undermost world itself. The kiva is a prominent feature of the archeological remains of the Southwest, there is seldom a mesa, cliff, or cavate ruin where these ceremonial chambers are not to be found. They are the substantial evidence of the worship of the cliff dwellers. The underground structures have undergone changes since the oppression of the invading Spaniard. In the Tewa village of San Hdefonso, for example, the under-ground circular kiva was abandoned after the first departure of the Spanish invaders; in fact, there is not a pre-Spanish building in the village. The ruins of the old village are barely distin-

FIG. 74.—Zuñi personators of the rain gods.  
Photograph by Mrs. Stevenson.

guishable in the fields, while the present village stands a short distance to the north. The first kiva constructed by these people after the coming of the Spaniards was round and built principally above ground, but before another kiva was constructed the people decided to build these chambers in rectangular form and in line with their dwellings, so that they would not be distinguished by the Spanish enemy. Many other pueblos adopted the plan of the rectangular kiva situated among the dwelling houses.

The Tewa are divided into the Sun and Ice peoples, therefore there are two kivas, one for each people. Every male child must be initiated into one of the kivas in order to be eligible to dance with the gods after death in the undermost world. The female child is passed

through impressive ceremonies by a priest of the kiva, just after birth, and is carried into the presence of the rising sun on the twelfth day. As the tiny infant is held up facing the sun the following prayer is offered to the Sun father: "May the child grow to womanhood; may she speak with one tongue, be gentle and kind to all, and may all be gentle and kind to her. May her life be so full of love for all the world, and may her acts be so pure that she may be blessed with the love of the Sun father, so that her span of life may be complete, that she may not die, but live long, and become a child again.

FIG. 75.—Learning to photograph. A fine likeness of the rain priest of the Ice People. The woman at the tub is his mother. Photograph by Mrs. Stevenson.

and so sleep, not die, to awake in the world with the gods. May she ever inhale more of the sacred breath of life."

In order that the rain priest may come into closer communion with the gods he must mortify the flesh. Semi-annually, at the winter and summer solstice, the rain priests of the Sun and Ice people retire, each with his associates, into the kivas for a retreat of four days and nights, to pray for rains, observing strict fasts, taking only meal-bread, and drinking popcorn water. Here it is that the rain gods are specially invoked. The rain priests do not pray with their lips—"hearts speak to hearts." While the priests practice deceptions upon the people and even delude themselves, when they leave their retreat,

it is evident from their expressions that their minds and bodies have been elevated above worldly thoughts.

Whence come the rains so devoutly prayed for? By direction of the Council of the Gods, the shadow people fill their vases and long-necked gourd jugs from the waters of the six regions, and, ascending to the upper plane, provided there are sufficient clouds to protect the rain makers from view of the people of this world, they proceed to water such portions of the earth as have been assigned to them by the Council. The Tewa priests have given such close observation to

FIG. 76.—Kiva of the Ice People, San Ildefonso. X shows upper entrance. Two trees are by the lower entrance. This kiva is headquarters for the buffalo ceremonial. Photograph by Mrs. Stevenson.

the winds and clouds that they are quite weatherwise, and seldom select a time for a rain dance, when rains do not follow.

Zoöic worship has to do with the healing of the sick, the beast gods acting as mediators between man and the anthropic gods. The most shocking ceremony associated with the zoöic worship of the Tewa is the propitiation of the rattlesnake with human sacrifice to prevent further destruction from the venomous bites of the reptile. The greatest secrecy is observed and the ceremonies are performed without the knowledge of the people except those directly associated with the rite which is performed quadrennially. Although many legends of the various Pueblos have pointed indirectly to human sacrifice in

the past, it was a revelation to Mrs. Stevenson when she was informed that this rite was observed by the Tewa at the present time; and, while it is said to exist only in two of the villages, she has reason to believe that they are not exceptions. In one village the subject is said to be the youngest female infant; in the other village an adult woman is reported to be sacrificed, a woman without husband or children being selected whenever possible. The sacrificial ceremonies occur in the kiva. The subjects are drugged with *Datura meteloides* until life is supposed to be extinct. At the proper time the body is placed upon a sand painting on the floor before the table altar and the ceremony proceeds amid incantations and strange performances.

FIG. 77.—Lucindra Jackson, Yonkalla tribe, Kalapuya family. Photograph from Frachtenberg.

The infant is nude, and the woman is but scantily clad. After the flesh has decomposed and nothing but the bones remain the skeleton is deposited, with offerings, beneath the floor of an adjoining room of the kiva. The entire ceremony is performed with the greatest solemnity.

#### NOTES ON THE ALSEA AND KALAPUYAN INDIANS

The opening of the year found Dr. Leo J. Frachtenberg in Siletz, Oregon, completing the linguistic and ethnological studies that were commenced in 1910 among the Alsea Indians. In addition to im-

FIG. 79.—William Smith, an Alsea Indian, about 65 years of age. Photograph from Frachtenberg.

FIG. 78.—Mary Harris, who died in 1910, the last of the Willapas. Photograph from Frachtenberg.

portant new linguistic material, he obtained a number of myths belonging chiefly to the Coyote cycle. This work was brought to a successful close towards the end of March.

In the early part of June he went to Bay Center, Washington, where he was told could be found, still extant, some members of the Willapa tribe, an important branch of the Pacific group of the

FIG. 80.— William Hartless, a Kalapuya Indian about 65 years of age. Photograph from Frachtenberg.

Athapascan family. Unfortunately, upon close investigation, these reported Willapas proved to belong to the Chehalis tribe of the Salish family, a circumstance that substantiated his previously expressed belief that the Willapa Indians are entirely extinct. Upon his return to Siletz, Oregon, Dr. Frachtenberg began work on the Kalapuyan family, collecting linguistic notes and mythological material until the middle of September, when the work had to be discontinued for lack of funds.

FIELD-WORK AMONG THE CATAWBA, FOX, SUTAIO, AND  
SAUK INDIANS

From a study of Siouan and Muskogean languages, it appeared that these stocks resemble each other morphologically as compared

FIG. 81.—The Brown Family, Catawba Indians. Photograph by Michelson.

FIG. 82.—Catawba Children. Photograph by Michelson.

with other American Indian languages. It therefore became a matter of importance that Catawba, a Siouan language of the Southeast, should be investigated to determine how close these resemblances were, and whether it was possible that both stocks were de-

rived from a common ancestor, but had differentiated at an early date. Accordingly, Dr. Truman Michelson of the Bureau of Ethnology left for South Carolina in May, 1913. Unfortunately, though a goodly number of individual words were collected, it was found that barely half a dozen persons were left who could give simple connected phrases, and only one or two who could give connected

FIG. 83.—An old Cheyenne who remembers a little of the Sutaio language. Photograph by Michelson.

texts, but upon examination it was found that even the few texts which Dr. Michelson collected were extremely fragmentary. Under these conditions it is likely that it will not be possible to unravel the structure of the language in detail, and hence the problems presented above remain unsolved.

In July, Dr. Michelson arrived in Tama, Iowa, to renew his researches among the Fox Indians. After making arrangements for

future work in August, he left for Montana to ascertain whether the Sutaio were a missing link connecting the Cheyenne with the normal Algonquian. The number of persons who remembered anything of the language were few, and none who could dictate connected texts were found. However, it seems clear from the individual words collected, that Sutaio will not shed any light on Cheyenne.

FIG. 84.— David A. Harris, Chief of the Catawba Tribe. Photograph by Michelson.

Upon his return to Iowa at the end of the month, he renewed his work with the Fox Indians. He was particularly successful in working out their social organization. A few more important myths were collected, and a number of those collected previously were translated. During his stay among the Foxes he also secured a number of ethnological specimens for the National Museum.

In October, Dr. Michelson left for Kansas to investigate the Sauk and Fox of the Missouri and adjacent tribes. A preliminary survey was all that was attempted owing to the inclemency of the weather. Some myths, obtained among the Foxes of Iowa, were also translated, and the investigator returned to Washington for office work.

FIG. 85.— A Catawba hearth with pottery. Photograph by Michelson.

#### EXPEDITION OF THE ASTROPHYSICAL OBSERVATORY

Mr. L. B. Aldrich proceeded to Mount Wilson in July, 1913, for the purpose of measuring the solar radiation. He was joined there at the end of August by Director Abbot. Several kinds of work were undertaken; first, the usual spectro-bolometric determination of the solar constant of radiation. This work has now been carried on during every summer at Mount Wilson from 1905 to 1913 inclusive, excepting the year 1907. It has resulted in showing an irregular variability of the sun from day to day, and a dependence of the sun's radiation on the number of sun-spots. It has also yielded a value of the solar constant of radiation believed to be correct within one per cent. Since there have been criticisms of the value, however, on the ground that it is impossible to correctly estimate the losses of radiation in the earth's atmosphere, it was felt desirable to check the result by sending up self-registering apparatus attached to free balloons to the highest possible altitudes.

This work was undertaken by Mr. Aldrich in coöperation with the United States Weather Bureau. Balloons were sent up on five days from Santa Catalina Island, carrying in each instance a self-registering pyrhelimeter devised and tested at the Smithsonian Astrophysical Observatory, and a self-registering apparatus of the Weather Bureau, which records the temperature, pressure, and humidity of the atmosphere.

All the balloons carrying pyrhelimeters were fortunately recovered, and in one instance the flight reached the altitude of about 33,000 meters, or 108,000 feet. The registering pyrhelimeters behaved very well with the exception that their temperature sunk lower than was expected, so that in each case the mercury in the stem of the

FIG. 80.—Observing station of Astrophysical Observatory on Mount Wilson with new tower telescope. Photograph by Abbott.

thermometers was frozen at an altitude of from 40 to 50 thousand feet, and therefore their records did not extend as high as the flights of the balloons. Nevertheless these measurements are obtained at altitudes above the highest clouds, and where the water-vapor and dust of the atmosphere is almost inappreciable. The results reached do not differ from what would be expected in view of the value of

the intensity of the solar radiation outside the atmosphere, as computed from the ordinary measurements of the Astrophysical Observatory. It is expected that the observations will be repeated with improved apparatus in the year 1914.

After the arrival of Mr. Abbot, the new tower telescope was completed and prepared for observations of the distribution of brightness over the sun's disk. A solar image of about 9 inches in diameter is formed in this telescope by the use of mirrors, without lenses. The distribution of brightness along the diameter of the disk is observed at different colors of light by means of the spectro-bolometer. It is found that the sun is much brighter at the center of the disk than

FIG. 87.—Diagram showing Brightness Distribution along Sun's Diameter.

it is near the edge, and that this contrast of brightness is greater for red light than for violet light.

The distribution of brightness along the sun's disk was observed on nearly 50 days, in connection with measurements of the intensity of the solar radiation as it would be outside the atmosphere. The results show in 1913, as in former years, a variability of the solar radiation from day to day. Along with this variability of the amount of the radiation, there is also shown a variability of the distribution of the brightness along the diameter of the sun's disk. This result is very interesting and important, for it enables the variability of the sun to be observed in two independent ways at the same observatory.

## INTRODUCTION

Since no one has ever collected the views of the various writers on the sense of smell in insects, the literature that bears directly on this subject is here briefly discussed for the use of students on this subject. Abstracts and translations of this literature have been made by the writer and his wife, Emma Pabst McIndoo, and the discussion is from these abstracts and translations. Minor details may have been incorrectly stated in some cases, but it is believed that each view as a whole is given correctly. The views of a few authors have been cited from others, because the original works were not accessible. After a short discussion of the sense of smell in general, the

names of the various writers and their views are grouped under heads according to the seat of the olfactory organs which these writers favor. A few writers fail to advocate any particular view but they criticize certain ones. Such writers are placed under the head which they criticize.

This discussion was originally written as the second part of the author's (1914a) paper on "The Olfactory Sense of the Honey Bee." On account of the great length of this paper it was necessary to omit the discussion. Since the first part of the paper was published a few more references have been collected and the author (1914b) has written a second paper on the same subject concerning the Hymenoptera. Several letters have also been received requesting that a complete discussion be published. Another reason for publishing this discussion is to reveal the chaos which now exists on this subject, so that students may hereafter replace such chaos by facts.

The author is grateful in various ways to Dr. E. F. Phillips, in charge of bee culture investigations, and to Miss Mabel Colcord, librarian of the Bureau of Entomology, for invaluable aid in securing references.

#### SENSE OF SMELL IN GENERAL

Aristotle is the earliest author whose writings on the sense of smell in insects are available. He says:

As for insects, both winged and wingless, they can detect the presence of scented objects afar off, as for instance bees and gnats detect the presence of honey at a distance; and they do so recognizing it by smell. Many insects are killed by the odor of brimstone; ants, if the apertures to their dwellings be smeared with powdered origanum and brimstone, quit their nests; and most insects may be banished with burnt hart's horn, or by burning of gum styrax.

Virgil was a beekeeper as well as a poet. The ancients used roasted or burnt crabs in the treatment of certain bee diseases, but Virgil warned beekeepers that the odors arising from such materials are injurious to bees. He also reports that certain strongly scented plants were rubbed on the tree where a swarm of bees was collecting, so that these odors might prevent them from going farther.

Pliny states that the odors of origanum, of common lime, and of sulphur kill ants. Gnats hunt for acids and do not approach things which are sweet.

Varro (1735) infers that bees can distinguish odors, and that they are sensitive to perfumes which come from odoriferous objects; in this respect their preferences differ greatly.

Æliani (1744) asserts that bees smell anything with a foul odor or anything smeared with odors, and that they cannot tolerate an offensive smell, nor do they like sweet, delicious odors.

Rösel and Klemann (1747) remark that it is clearly understood that certain butterflies have a very acute sense of smell and that one sex certainly perceives the odor of the other from a distance.

Romanes (1877) is certain that moths smell, although they may detect the odor from ammonia through their whole system.

The Peckhams (1887) in their experiments on wasps used two essential oils—peppermint and wintergreen—maple syrup, and warm and cold chicken bones. They say:

We conclude from these experiments that wasps have a strong sense of smell, but that they pay little attention to odors, however powerful, which do not denote the presence of something which they can utilize as food.

From the foregoing it is evident that the belief in a sense of smell in insects is general and that some insects are able to distinguish between various odors. From the time of Aristotle to the present no one has ever denied that insects can smell, yet no one has ascertained the relative sensitiveness for any particular species.

#### SPIRACLES AS SEAT OF OLFACTORY ORGANS

Sulzer in 1761, according to Lubbock (1899), was the first to suggest that the spiracles are the seat of the olfactory organs. Later, however, he abandoned this view and adopted the antennal theory in 1776.

Dumeril (1797) asserts that all insects possess a more or less acute sense of smell. He was the first to advocate strongly the view that insects, like all other animals that live in the air, have their olfactory organ located at the entrance of the respiratory system. The air charged with odoriferous particles passes into the tracheæ through the spiracles and here these particles stimulate multitudes of nerves and thus the sensation of smell is produced. He thought that the tracheal walls consist of a membrane which is clothed with olfactory nerves, against which the odoriferous particles from foreign bodies strike. Later the same author (1823) remarks that the perception of odors is then, like all the other sensations, physical—a kind of touch in which the bodies, should that be their nature, impinge upon the olfactory nerves. Dubois (1890) held the same opinion, saying that the first excitation is a mechanical one, like that which occurs in the sensation of touch. Hermbstädt (1811) asserts the opinion

now generally prevalent, that taste and smell are chemical senses, while sight, hearing and touch are purely mechanical.

Baster (1798), cited from Perris (1850), believes that olfactory stimuli are received by the tracheæ, either at their apertures or throughout their whole extent.

Lehmann (1799), according to Lacordaire (1838), was the first who actually performed experiments to determine the location of the olfactory apparatus. He made a round aperture, surrounded by wax, in a glass bottle, in the center of which was a paper diaphragm. The antennæ or entire head of an insect was then inserted into this aperture. He next introduced into the bottle strongly odoriferous substances, such as burnt feathers, burning sulphur, etc. None of the insects subjected to this test reacted, but when the same substances were placed near the remaining part of the insect, the specimen made violent movements which showed the effect these substances had upon it. He concluded, therefore, that the head is not the seat of olfaction and that it must lie in the tracheæ near their external openings. As the antennæ are covered with hard chitin, while the tracheal walls are clothed with very thin, chitinous membranes, critics contend that such strong irritating odors mechanically irritate the tracheæ and that these odors cannot so affect the antennæ on account of the hard chitin.

Cuvier (1805) thinks that since all other air-breathing animals have the organs of smell located at the entrance of the respiratory organs, we should find it at the entrance of the tracheæ in insects, as Baster suggested. He added that the internal membrane of the tracheæ, being moist, appears properly to fulfill this office, and that in the insects in which the tracheæ form numerous vesicles these tracheæ appear to be excellently suited for the seat of smell. The antennæ do not seem to fulfill any of these required conditions.

Straus-Durckheim (1828) believed that the seat of olfaction is located at the entrance of the tracheæ because he discovered, in the environs of the spiracles, nerves which are large enough to belong to a special sense organ.

Lacordaire (1838), after discussing the experiments of Huber and Lehmann, says that from all the preceding we can conclude that we know nothing positive about the seat of smell and that the hypothesis which locates it in the respiratory organs is yet the most rational of all.

Brullé (1840), after briefly discussing the sense of smell in articulate animals, remarks that the organ of smell is not known in these

animals, unless it is to be assigned to the apertures of the respiratory organs.

Of the foregoing six authors who advocate the theory that the spiracles are the seat of olfaction, Lehmann is the only one who experimented on the subject. The others seem to think that an analogy with higher animals is sufficient proof. Lehmann's experiments indicate that the seat of smell is not located in the head and assumes that the tracheæ are the only other place in which these organs could be located. No one has found any nerves or any kind of sense organ, which suggest an olfactory function, in the walls of the tracheæ or in the spiracles of the bee. This theory has been long since abandoned.

#### STRUCTURE NEAR SPIRACLES AS SEAT OF OLFACTORY ORGANS

Joseph (1877) postulated three conditions necessary for an olfactory apparatus: (1) It must come in contact with moving air; (2) it must be continually moistened, and (3) the olfactory substance must be in the form of a gas. If one of these three conditions is lacking, olfaction is impossible. According to these conditions no one has sought the seat of smell in any place other than at the entrance of the tracheæ, and the assumption that insects smell with their antennæ or buccal organs is completely inadmissible. In spite of the fact that their antennæ had been removed and in spite of their clumsy flying, a number of *Necrophorus vespillo* (carion beetles) found a carcass wrapped in paper at a distance of 20 feet. The same result was obtained with the flesh-fly (*Musca Sarcophaga carnaria*) and with other insects. A short distance from the spiracles, toward the median line of the thorax and abdomen, he reports finding a peculiar structure which he called the "regio olfactoria." This olfactory region is completely covered by a delicate membrane perforated by pores, the largest of which are for gland exits and the smallest for hairs. Beneath this membrane lies a peculiar layer of cells.

Thus, not favoring the view that the spiracles are the seat of smell, and in order to comply with the above three conditions, Joseph assumed the existence of an organ near the spiracles which communicates with the air cavities of the tracheæ. Of course, being connected with the tracheæ and being continually moistened by the glands, it is easy to see that the necessary conditions would be fulfilled. No drawing of this organ is given and no such structure is found in the honey bee.

GLANDS OF HEAD AND THORAX AS SEAT OF OLFACTORY  
ORGANS

Ramdohr (1811) states that many species of insects, and among them the bee, have a well-marked sense of smell. He failed to find olfactory organs in the spiracles, but conceived the idea that odors come into the mouth through the lumen of the proboscis. He found behind the mouth a tube which is divided into three branches, the smallest of which runs along the cesophagus above the first thoracic ganglion and soon divides into two smaller tubes which pass into the thorax and seem to connect with the large tracheæ coming from the first spiracle. The other two branches pass at right angles into the sides of the head, where they expand into four small sacs which differ from air tubes in having walls that are soft, thick and transparent. A thick tissue of the finest tracheæ covers these various tubes. Ramdohr also mentioned nerves running to his supposedly olfactory organ. He was led to believe that air carrying odors passes through the lumen of the proboscis into these small sacs and, as their walls are soft and perforated with minute air tubules, that they act as an organ of smell. Referring to Snodgrass (1910) and judging from the foregoing description, Ramdohr probably mistook the thoracic salivary gland for the branch accompanying the cesophagus, and the salivary glands in the posterior part of the head for the other two branches.

## CESOPHAGUS AS SEAT OF OLFACTORY ORGANS

Treviranus (1816) infers that the smelling organs in various families of insects are located in the throat. In all the insects discussed the cesophagus is dilated, as in the bee, in front of the stomach into a large sac-like reservoir, which he thought is perhaps for the purpose of drawing air into the throat. He believed that in the presence of strong-smelling substances the antennæ do not produce noticeable movements. He further stated that the olfactory apparatus of higher animals and the antennæ and palpi of insects are as different in structure as organs can ever be. In order to smell, higher animals must inhale the odoriferous particles. On the contrary, the antennæ and palpi do not conform with this general rule; in most insects these appendages are not coated with a mucous skin and the interior is carefully guarded against the entrance of odoriferous air. Treviranus therefore infers that the sac-like reservoir "honey stomach" in the bee, is for the purpose of drawing odorous air into the cesophagus.

### "INTERNAL SUPERIOR SURFACE" AS SEAT OF OLFACTORY ORGANS

After discussing the various views concerning the location of the organs of smell, Burmeister (1836) concludes as follows:

Thus insects, according to my opinion, would smell with the internal superior surface, if I may so call it, which is provided all over with ramifications and nets of nerves, since this is always kept moist by the blood distributed through the body and by transpired chyle, the same as is surmised of the superior *Molusca*.

Further, the same authority wrote.

Various authors consider the antennæ as olfactory organs, but with what right? A hard, horny organ, displaying no nerve upon its surface, can not possibly be the instrument of smell, for we always find in the olfactory organ a soft, moist, mucous membrane, furnished with numerous nerves.

What Burmeister means by "internal superior surface" is not clear.

### DIFFERENT PARTS AS SEAT OF OLFACTORY ORGANS

Schelver (1798), cited from Lacordaire (1838), and Comparetti (1800), according to Perris (1850), place the seat of smell in different parts for different families, as follows: The club of the antennæ in lamellicorns, the proboscis in the Lepidoptera, and certain frontal cells, which have never been seen since by any one else, in the Orthoptera.

### FOLDED SKIN BENEATH ANTENNÆ AS SEAT OF OLFACTORY ORGANS

Rosenthal (1811), cited by Burmeister (1836), "described a folded skin at the forehead, beneath the antennæ, to which two fine nerves passed, and which he considers the organ of smell in the flies *Musca domestica* and (*Musca*) *Calliphora vomitoria*; and he observed, after the destruction of the part, a deficiency of the function which had previously strongly exhibited itself."

The honey bee has no such structure as that described by Rosenthal.

### RHINARIUM AS SEAT OF OLFACTORY ORGANS

Kirby and Spence (1826) regard the rhinarium as the location of the organs of smell. The rhinarium or nostril-piece is the foremost portion of the clypeus just above the labrum; it consists of circular pulpy cushions, covered by a membrane transversely marked with fine striæ. These fleshy cushions, like the upper surface of the tongue, are beset with minute black tubercles carrying bristles.

No such structure as the rhinarium exists in the bee.

PLATE BETWEEN EYES AND BENEATH ANTENNÆ AS SEAT OF  
OLFACTORY ORGANS

Paasch (1873) claims that no nerves coming from the brain lead to the tracheæ and that the olfactory organ need not necessarily be connected with the breathing apparatus. He reasons that its location should correspond with that found in higher animals. He found a peculiar plate situated between the eyes and beneath the antennæ and extending to the base of the proboscis. This plate possesses a groove whose edges are beset with stiff bristles, and many tracheal branches; it also has nerve connections. This he regards as the olfactory organ. This plate does not exist in the honey bee.

## MOUTH CAVITY AS SEAT OF OLFACTORY ORGANS

After having cut off the antennæ of some queen bees, Huber (1807) was rather inclined to regard these appendages as the olfactory organ, but later (1814) after many experiments he concluded that the organ of smell resides in the mouth itself or in the parts depending upon it.

The following is a brief summary of his later work concerning the olfactory sense: Not only do bees have an acute sense of smell, but they possess the memory of sensations. For example, in the fall we placed some honey in a window and the bees came to it in great number. The honey was removed and the shutter of the window was closed all winter. The following spring, when we opened the shutter, bees returned to the same window, although there was then no honey at this place. They remembered that it had been there previously and an interval of several weeks had not effaced the acquired impression. Bees not eating appear more responsive to odors, while those eating honey are reluctant to move when odors are brought near them. To ascertain how different odors affect bees he used mineral acids and volatile alkalies presented on a pencil brush to the opening of the mouth; these did not affect them. Musk placed in front of the hives did not irritate the bees much. Assafoetida mixed with honey was put at the entrance of hives; the bees ate the honey and were not annoyed by this odor which is obnoxious to us. Bees are greatly affected by the odors from camphor and the poison from bee stings.

To locate the region of the body in which the olfactory organ is found, Huber brought a pencil brush, which had been dipped into turpentine oil, near the abdomen, thorax and head. He saw a response only when it was in the region of the head and decided that the organ of smell is located only in the head. He next placed an ex-

tremely fine pencil brush wet with the same oil near the eyes, antennae, proboscis and mouth cavity. The only response observed was when the brush came near the mouth cavity. He obtained the same result, only more pronounced, when oil of origanum was used. The mouths of several bees were filled with flour paste and when this was dry they were released. Honey, turpentine and oil of cloves, either in fixed or volatile alkalies, did not produce any response.

#### EPIPHARYNX AS SEAT OF OLFACTORY ORGANS

Wolff (1875) found many peculiar hairlike organs on the epipharynx of the honey bee; each organ consists of a small cone with a pit in the summit bearing a small hair. He regarded these cones as having an olfactory function and believed that the mandibular glands pour a liquid upon the surface of the epipharynx which keeps these cones moist and capable of absorbing odoriferous particles. He explained the inhalation of these particles into the preoral cavity as brought about through the contraction of the air sacs situated near the mouth.

Harting (1879), in discussing Wolff's olfactory organs, inferred that Wolff tried to homologize the epipharynx with the nose of higher animals whereas there is not the slightest reason for such an homology.

To determine whether the mouth cavity and the epipharynx are the seat of the olfactory organs, the author repeated Huber's experiment of filling the mouth cavity with flour paste. With the aid of a small pencil brush the mouth cavities of 20 worker bees were thus filled. When the paste had become perfectly dry, the bees were put into observation cases. They seemed otherwise entirely normal, but lived only  $7\frac{1}{2}$  days as an average, whereas un mutilated workers in the same cases lived 9 days and 3 hours. When tested with the oils of peppermint, thyme and wintergreen, their average reaction time was 2.68 seconds. The average for the same odors with normal workers was 2.64 seconds. It would seem that neither the buccal cavity nor the epipharynx has anything to do with olfaction.

#### PALPI AS SEAT OF OLFACTORY ORGANS

Lyonnet (1745) thinks that the palpi should be considered as the organs of smell rather than those of taste.

Bonnsdorf (1792) and Knoch (1798), according to Perris (1850), regarded the palpi as olfactory organs, but Knoch believes that the maxillary palpi only are for smell, while the labial palpi are for taste.

According to Marcel de Serres (1811), even if insects have their olfactory organs located at the entrance of the respiratory organs, the view that the palpi serve as organs of smell does not contradict the former view, because the palpi communicate both internally and externally with the air. This view resembles Duponchel's theory (1840), except that the latter author considers the antennæ of certain water insects as having a respiratory function. Duponchel thought that the antennæ were provided with minute perforations through which the air passed.

Newport (1838) performed many experiments with certain insects (*Sylphæ*) and he concludes that they find their food by smell but he did not think that the olfactory organs are found either in the antennæ or spiracles. He says:

Hence, I think it must appear \* \* \* from the motion of the palpi and the avidity with which the insect darted upon the food when held in front of it, it seems but fair to conclude that the sense of smelling must certainly reside in the head.

We may include Newport with those who believe that the palpi are the seat of olfaction.

Driesch (1839) favors the opinion that the seat of the olfactory organ is located in the palpi.

Perris (1850) found that after the amputation of the palpi insects showed none or only a very little sensibility to odors. In the articulates the sense of smell resides in the antennæ and in the palpi; but the antennæ are destined to perceive odors from both afar and near, while the palpi perceive odors from afar only. As far as the palpi are concerned he thinks that the seat of smell lies in their last joint. Cornalia (1856) also shared this view.

Plateau (1885) performed many experiments by cutting off the palpi. He ascertained that the amputation of both maxillary and labial palpi did not destroy the olfactory sense.

Wasmann (1889) favors the view that the group of delicate peg-like papillæ on the tips of the palpi probably function as olfactory organs.

To ascertain whether the palpi of the honey bee bear the organs of smell, the author cut off the labial palpi and maxillæ of 19 workers at their bases. When put into observation cases these bees appeared normal in all other respects, but certainly were not completely normal, for they lived only 24 hours on an average. When tested with the oils of peppermint, thyme and wintergreen, honey and comb, pollen and leaves and stems of pennyroyal their average reaction time was 4

seconds, whereas for the same odors with unmutilated bees the average was 3.4 seconds. Since these appendages carry several porelike organs, we may either attribute the 0.6 second difference in reaction time to the view that these appendages really aid in receiving odor stimuli, or to the injury caused by the operation, or to both of these views combined.

Breithaupt (1886) describes some porelike sense organs on the base of the proboscis of the bee. To determine whether these have an olfactory use, the author cut off the proboscides of 22 workers. These bees seemed normal in most respects, but lived only 7 hours on an average. When tested with the oils of peppermint, thyme and wintergreen the average reaction time was 2.9 seconds, while for the same odors with unmutilated bees the average was 2.6 seconds. We can probably attribute this difference of 0.3 second to the abnormality of the mutilated bees.

Janet (1911) describes a sense organ in the mandible of the honey bee which he thinks may have an olfactory function. To ascertain this experimentally, the mandibles of 20 workers were amputated close to the base by the author. These bees appeared completely normal, although they lived only 7 days on an average. When tested with the oils of peppermint, thyme and wintergreen, honey and comb, pollen, and leaves and stems of pennyroyal, they gave an average reaction time of 4.8 seconds, while the average for the same odors with unmutilated bees was 3.4 seconds. We may attribute this slight difference in reaction time either to the injury caused by the amputation, or to the view that the mandibles help to perceive odors, or to both.

## ANTENNÆ AS SEAT OF OLFACTORY ORGANS

### (1) WITHOUT EXPERIMENTS

Reaumur (1734) was the first to suggest that the olfactory organs of insects lie in their antennæ.

Lesser (1745) says that the sense of smell of some insects is more acute than that of man. He gives as two proofs of this, (1) that they find their food with this sense, (2) that they scent food farther than man does. He says that the antennæ are "noses" and that they enable their owners to smell odors near or far away.

Baster (1770) remarks that no one doubts that insects can smell, for flies, purely through olfaction, find their way to tainted meat. He also states that water insects can smell. Baster states that no insects, whether living in the air, under water, or in the earth, have the seat of smell in the antennæ.

Sulzer (1776) contends that insects have an acute sense of smell and spoke of bees coming for honey when it is placed in a spoon under a window. He believes that the olfactory apparatus is located in the antennæ.

Fabricius (1778) infers that the seat of smell belongs to the antennæ.

Bonnet (1781) asserts that diverse insects have the sense of smell exquisitely developed, but that we do not know where the seat of this sense lies. He suggests the antennæ as a possible location.

In discussing the probable uses of the antennæ, Olivier (1789) regarded them as olfactory in function.

Latreille (1804) regards the fact that many male insects have the antennæ better developed than the females of the same species as evidence that these appendages are the seat of olfaction. The greater number of insects that live in animal matter, in decayed vegetables, or in stagnant water generally have the antennæ better developed than those that live elsewhere. A more perfect olfaction would be necessary to these insects, and the organization of the antennæ seems to be adapted for this purpose.

After discussing Marsham's account of ichneumon flies, Samouelle (1819) states, "From these remarks may we not infer that the antennæ may be the organ of smelling?"

De Blainville (1822) and Robineau-Desvoidy (1828), cited from Perris (1850), state that the antennæ are olfactory organs.

After briefly discussing the various views concerning the seat of olfaction, Carus (1838) confesses that the opinion of Rosenthal, combined with that of Réaumur, appears to him to be the best. Hence he believes that the seat of olfaction lies in the folded skin beneath the antennæ as well as on the surface of the antennæ.

Since the antennæ of the male are often better developed than those of the female, Percheron (1841) states that the antennæ of the male aid the eyes in searching for the female. He infers that the antennæ are used for smelling.

Goureat (1841) thinks that the antennæ may be organs of olfaction besides being organs of touch and hearing.

Pierret (1841) also favors the view that the seat of olfaction lies in the antennæ.

Robineau-Desvoidy (1842) speaks of an olfactory apparatus as nothing less than an ordinary organ of touch which is capable of receiving invisible stimuli. By analogy he thinks that the antennæ must be the organs of smell.

Slater (1848) firmly believes that the antennæ are olfactory organs. He says that the antennæ seem to be the real organs for this sense or for a sense closely allied to it.

According to Dufour (1850) both the organs of audition and olfaction are found on the antennæ. The distal joints, which have a spongy texture, are the ones that bear the sense of smell, for here the odoriferous atoms can fall upon this special texture and the impulse can be transmitted to the cerebral ganglion.

Claparède (1858) asserts that absolutely nothing warrants us in locating in the antennæ the sense of hearing rather than that of olfaction or any other function, but he favors the view that the organs of smell are there.

Dönhoff (1861) from various experiments contends that bees learn the location of honey and of the queen through the antennæ. He placed a stick near the antennæ of a bee and these appendages remained quiet. When a stick wet with honey was similarly placed, the bee at once extended these appendages in the direction of the stick. When one places a foul-smelling substance like tobacco juice near the antennæ, the bee moves away. When one places a stick wet with honey or tobacco juice near a bee with amputated antennæ the insect shows no response of any kind. He thinks that the olfactory organ was removed by cutting off the tip of the antennæ.

Noll (1869) asserts that butterflies have a fine sense of smell as shown by the way in which they find prepared food when placed in a box covered with screen wire and having only a slit through which these insects may enter. This is shown by the way in which the males are able to find the females. He regards the antennæ as the olfactory organs, at least for the male.

Woufor (1874) says:

That it is the sense of smell which directs the blow-fly to the deposition of the larvæ is shown by the fact that she has laid them on *stapelias*, a carrion-odoured hothouse plant, and on silk with which tainted meat had been covered. Notwithstanding the view of Hicks he considers one of the functions of the antennæ as that of smell.

Fabre (1882) remarks that it is incontestable that insects have a very highly developed sense of smell. Carrion beetles run from all sides to the place where a dead mole lies. If we admit that the seat of smell lies in the antennæ he contends that it is difficult to comprehend how such an appendage of hard chitinous rings, articulated end to end, is able to fulfill the office of a nose. The organization of a true nose and that of the antennæ have nothing in common.

Henneguy (1904) state that the organ of olfaction is probably located in the antennæ and the buccal palpi.

## (2) WITH EXPERIMENTS

Dugés (1838) was the first to experiment with the antennæ of insects. He cut off the antennæ of two male (*Bombyx*) *Eudia paronia minor* and then these insects were unable to find a female that they had previously been able to locate while their antennæ were intact. Also, after having extirpated the antennæ of many blow-flies, (*Musca*) (*Calliphora vomitoria*), and a large viviparous fly, *Sarcophaga carnaria*, he ascertained that they were unable to find putrid meat as before. He felt satisfied that olfaction resides in the antennæ.

Lefebvre (1838) was the first observer to experiment with a *bee*. He placed a long needle, whose end had been plunged into ether, near a piece of sugar which a bee was eating. The bee moved its antennæ towards the needle and then passed them several times between the legs. He brought this needle near the legs and spiracles, and since he noticed no response from these parts, he concluded that the antennæ are olfactory organs. As a control he used a needle without ether in the same manner. Next he mutilated the antennæ of several wasps (*Vespa*). All their organs for perceiving odor stimuli seemed to be at the extremity of these appendages.

Küster (1844) declares that bees have a very acute sense of smell. He reports some that found a store of honey; even a week after they had carried away all the honey they still continued to come to the same place in search of more food. Since vertebrates carry their olfactory organs on the front of their head, under and between the eyes, he tried by analogy to locate the corresponding organs of the bee on the antennæ.

Perris (1850) repeated Dugés' experiment by holding many specimens of different families and genera over the mouths of vials containing alcohol, turpentine, or ether. At times he obtained the same results as did Dugés, at other times none at all, using the same individuals after intervals of one-half hour; but more often the antennæ or palpi exhibited more or less violent movement. He also repeated the experiments of Huber on various insects by stopping up their buccal cavities with wax, paste and gum. When they were set free he did not notice any signs of inconvenience. By such experiments he failed to locate the seat of the organs of smell in or near the mouth as Huber did. After having placed a brush dipped in turpentine, ether or wild thyme near the spiracles he concluded that odor-stimuli are not received by the respiratory apparatus.

In his summary Perris says: (1) By amputating the extremity of the antennæ the olfactory sense is not destroyed but it is weakened,

and by cutting them off at the base the sense of smell is totally or partially destroyed; (2) covering the antennæ with a layer of india rubber renders these organs insensitive; (3) sometimes a little sensibility is shown when the palpi are amputated. Thus in the articulates the organs of smell reside in the antennæ and in the palpi, but the antennæ recognize odors from afar and from near by, while the palpi recognize only distant odors. In the plumose, flabellate or pectinate antennæ olfactory organs are present in all the branched parts. In the simple and setaceous or filiform antennæ the organs of smell are principally in the last joints and diminish toward the base. In antennæ terminated with a club the organs of smell are exclusively in the club. He believes that the organs of smell are present in the last joint of the palpi.

Cornalia (1856) says that the manner in which insects move the antennæ shows that these appendages serve for searching when the odor is scattered. He observed a male *Bombyx mori* that was trying to enter a small box in which a female was enclosed. After he had cut off the antennæ of this male it approached the box with uncertainty and sometimes did not go to the box at all. The same result was obtained by covering the antennæ. His view is similar to that of Perris in that the seat of olfaction lies in both the antennæ and palpi.

Garnier (1860) is certain that articulated animals perceive odors. Bees that go foraging for a long distance quickly recognize their hives without the aid of their acute vision. An organ of olfaction, wherever one may observe it, is an expansion of very fine skin, abundantly supplied with vessels and nerves, and moistened with a viscid fluid which permits the intimate contact of the odor. He does not state where the olfactory apparatus lies in insects, but he denies that the antennæ performs such a function, because when the knobs of the antennæ or the entire antennæ of individuals of the Genus *Necrophagus* were detached, the insects returned immediately to the body of a mole from which they had been temporarily removed.

Balbani (1866) put unmutated female butterflies in one box and in a second box he placed males of the same species. Some of the latter had their antennæ cut off. As soon as the box containing the females was placed under that of the males, the unmutated males moved their antennæ, vibrated their wings and quickly moved their legs, while the mutilated ones remained perfectly quiet. In this experiment he says that sight and hearing were excluded and thinks that olfaction brought about by the antennæ is entirely responsible for these responses of the males.

Forel (1874, 1885) says that myricids (ants) appear to have the sense of touch highly developed in the antennæ, while in the antennæ of *Tapinoma* (ants) the sense of smell is better developed. If individuals of either genus are deprived of their antennæ they cannot guide themselves and are not able to distinguish companions from enemies or even to discover food placed at their sides. While deprived of the anterior part of the head and of the entire abdomen they preserve all their faculties. The same author (1878a) claims that the moving-back and forth of the wings enables insects to scent certain substances by means of their antennæ. Olfaction may cause certain flying insects to proceed in a given direction.

Forel (1878b) used three wasps that had previously fasted. The first was left intact, both antennæ of the second were cut off, and the anterior part of the head up to the compound eyes of the third was cut off. After a short rest a needle dipped in honey was brought near the first insect. It at once directed both antennæ toward the needle with rapid movements and followed the needle when it was slowly moved away. Exactly the same thing took place in the wasp with the anterior part of the head cut off, and thus with the nerve endings of the mouth, the pharynx, and Wolff's olfactory organs lacking. It was quite different with the one with the removed antennæ. It remained near the needle motionless, did not react to honey at all, and did not follow the needle.

Forel (1908, p. 92) cites some of his experiments performed in 1878. He found the putrid bodies of a hedgehog and a rat infested by a swarm of carrion-feeding beetles belonging to several genera. He collected more than 40 specimens from the carcasses and removed their antennæ. Then he placed them all at one place in the grass and moved the dead bodies a distance of 28 paces from the beetles and concealed them in a tangle of weeds. Examination the next day revealed the fact that not one of the mutilated beetles had found the carcasses, and repeated experiments gave the same results. No beetle without its antennæ was ever found on the dead animals, although at each examination new individuals of the several species were present. On the supposition that the mutilation itself might make the beetles abnormal to such an extent that they did not care to eat, Forel next cut off all the feet on one side of the body from a dozen beetles with their antennæ intact and changed the location of the dead bodies again. The next day five of this lot were found on the carcasses.

Trouvelot (1877) performed various experiments on the antennæ of many butterflies, several *Promethes* silkworm moths, and some

ants. From these experiments he concludes that the antennæ are the organs of smell, but he thinks that the sense of smell in insects is very different from that sense in the human species. He regards it as a kind of feeling or smelling at a great distance by some process now entirely unknown.

Layard (1878) relates the experiments of a certain French naturalist who immersed a long-snouted weevil in wax so that it was covered all over except the tip of the antennæ. When tested with oil of turpentine it became violently excited and endeavored to escape. Another had only the tips of its antennæ coated with wax, and neither turpentine nor any other strong-smelling substance affected it. From this he infers that the organ of smell is present in the tips of the antennæ of weevils.

Slater (1878) says:

That wasps have an acute scent and seek their prey or their food by its means, will be generally admitted \* \* \*. When a wasp is flying it keeps its antennæ advanced and extended, so as to be in the most favourable position for receiving an impression from odoriferous substances.

Chatin (1880) states that when one brings a needle wet with ether, creosote, essence of wild thyme, or clove oil near the head of a bee it moves its antennæ, vibrates them vigorously, and directs them away from the odorous substance; if one repeats the same experiments near the spiracles no such movements are manifested. Also, when the antennæ are cut off no responses occur.

Lubbock (1882) experimented with a large female ant. He placed a feather of a pen almost against the antennæ of this ant without it moving in the least. Next he dipped the pen in essence of musk and repeated the experiment. The antennæ were at once retracted. With a second ant he used essence of lavender and observed the same results. Many more of his experiments indicate that ants have a highly developed sense of smell.

Porter (1883) experimented on a butterfly with a piece of gum camphor on the end of a broom straw. He says:

Whenever I put the camphor end near to its head and mouth parts, it would begin to struggle with all its might to get away from the fumes of the camphor; thus showing not only that it disliked the smell of camphor, but also that it did not smell with its antennæ. After experiments have shown the same thing of other insects.

This butterfly was affected little, if at all, by the extirpation of its antennæ while some humble bees become very sick after the loss of their antennæ; they, however, recovered after awhile. Some other humble bees are not affected at all by such an operation.

Graber (1885) severely criticizes the view that the antennæ are the seat of the olfactory sense. He experimented on many species with various odors, and makes the following claims: (1) Ants (*Formica rufa*) and flies (*Lucilia caesar* L.) without antennæ still possess the sense of smell; this fact shows that the perception of odors is not accomplished by the antennæ alone. (2) In *Silpha thoracica* deprived of antennæ, the odor of the essence of rosemary is manifestly perceived, while assafoetida does not affect the insects at all. Thus the antennæ are those parts of the body which are most sensible to odors. (3) From the comparative experiments on the excitability of the antennæ, the palpi, and the cerci (caudal styles) in *Gryllotalpa gryllotalpa* L. (*vulgaris*), the palpi are more sensible to odors than the antennæ. (4) The palpi of *Lucanus* are sometimes the most easily excited, at other times the antennæ, according to the odors employed. From similar experiments on *Periplaneta*, some intact, others several days after they were operated on, it seems that the reception of odor stimuli is accomplished by the cerci. Graber is inclined to the view that insects do not have any special olfactory organ, and that when the odoriferous emanations are intense they may be perceived by the surfaces of the body that are covered with thin chitin and provided with terminal excitable nerves.

Plateau (1886) used four *Blatta* (cockroaches), two with their maxillary and labial palpi cut off and their antennæ left intact and the other two with the antennæ cut off and the palpi left intact. These four insects were put into a large circular dish 8 inches in diameter. This vessel contained a bed of fine sand and in the center there was a round pasteboard box 2 inches in diameter and 2 inches high. Food was put into this box, and these insects were observed each day for a month. Each day he saw one or two *Blatta* eating the food, and in every instance these were the insects with un mutilated antennæ, and he concluded that the antennæ are the olfactory organs in *Blatta*.

Graber (1887) repeated Plateau's experiments by using many cockroaches and declares that it is sufficiently proved that cockroaches deprived of their antennæ smell little or none at all, and that the antennæ in these insects actually function as olfactory organs. He also says that for cockroaches (and some other insects) it is shown that the olfactory sense lies in the antennæ but this is not the case in all insects.

Dubois (1895) touched the scent glands situated at the tip end of the abdomen of a female moth with a glass rod and then brought this rod, which had no odor perceptible to him, near a male of the same

species that had its antennæ cut off. The male at once vibrated its wings and started toward the rod.

Fielde (1901a), who has made a special study of ants, claims in her various papers that ants have a keen sense of smell. The same author (1901b) asserts that,

The power of perceiving the individual track lies in the tenth segment of the antennæ. When deprived of this segment the ant is no longer able to find her way in with the pupæ, but wanders about helpless and bewildered. Ants deprived of nearly all of the eleventh and twelfth segments continued to carry the pupæ through the runs of the maze, though with diminished physical vigor. The ant could pick up her scent so long as a tenth segment was intact, and no longer.

Miss Fielde clipped the antennæ with sharp scissors and 15 days after the operation about 40 per cent of the ants recovered from the effect of the shock.

Before their recovery the ants were listless and abnormally irritable; and they attacked with self-destructive violence any moving thing that touched them. One antennæ performs all the functions of a pair. \* \* \* Every *Stenamma fulvum piceum* has an odor manifest in all parts of her animate body, and discerned by herself and by other ants through the eleventh segment of the antennæ.

The commingled odors of all the ants in the nest constitute what she calls the "aura" of the nest.

It is diffused in air or ether from the animate occupants of the nest, and it is discerned by the ant through the twelfth, the distal, segment of the antennæ.

When deprived of the distal segment the ants were not alarmed when introduced into the nest of aliens; they did not flee, nor did they endeavor to hide; thus their behavior is strikingly different from that of unmutated ants. Also she found (1907) that queens deprived of their antennæ did not behave normally.

So long as the eighth and ninth segments of the antennæ are uninjured, the ant may continue to lift and care for the eggs, larvæ, or pupæ, but after the removal of these segments she loses all interest in the young and performs no further work in the nursery. \* \* \* Marked ants of two hostile colonies, when clipped across the tenth segments, associated freely and amicably with one another during several days in the care of the pupæ belonging to one of the two colonies.

A paper by the same author (1903a) summarizes the foregoing and adds observations on some of the segments not heretofore mentioned. The following perceive these particular odors: The eleventh or distal segment, the nest odor; the tenth, the colony odor; the ninth, the individual track; the eighth and seventh, the inert young; the sixth

and fifth, the odor of enemies. Miss Fielde (1903b) claims that feuds between the same species living in different communities are caused by a difference of odor. Also, (1904) fear and hostility are excited by a strange ant odor. She (1905) decides that ants have a specific and progressive odor; the former is received by organs near the proximal end of the funiculus, while the latter is received among ants by organs in the penultimate joint of the funiculus.

Piéron (1906), basing his conclusion on the interpretations of Fielde and others, remarks that recognition in ants by odor is well established, and that sections of the antennæ have shown that the organs of smell are those of recognition.

Wheeler (1910) believes that the olfactory organs of ants are located in the antennæ, but he refutes Miss Fielde's theory that each segment of the antenna perceives a particular odor. He asserts:

She says: "The organ discerning the nest-aura, and probably other local odors, lies in the final joint of the antenna, and such odors are discerned through the air; the progressive odor or the incurred odor is discerned by contact, through the penultimate joint; the scent of the track by the antepenultimate joint, through the air; the odor of the inert young, and probably that of the queen also, by contact, through the two joints above, or proximal to those last mentioned, while the next above these also discerns the specific odor by contact."

This statement not only lacks confirmation by other observers, but seems to be the only one which implies that the olfactory organs of an animal may exhibit regional differentiations. This has not even been claimed for dogs, which nevertheless possess extremely delicate powers of odor discrimination and association. This would be no serious objection, however, if we were able to discover the slightest support for Miss Fielde's hypothesis in the structure of the antennæ. We do, indeed, find in the funiculi a variety of sensillæ, as has been shown in Chapter IV, but none of these is confined to a single joint or to two joints. Miss Fielde, moreover, completely ignores the tactile organs of the antennæ and makes this surprising statement:

"During five years of fairly constant study of ants I have seen no evidence that their antennæ are the organs of any other sense than the chemical sense."

Many of her interpretations of the behavior of ants with mutilated antennæ are open to the obvious objection that she tacitly denies the existence of perception where there is no visible response or where the animal inhibits certain of its activities. If we add to this objection the very limitations of the method, *i. e.*, the necessity of removing all the joints distal to the one whose function is being tested, and the consideration that the hypothesis is not needed to explain the facts, it will be seen that we are not sufficiently justified in regarding the ants' antenna as an organ made up of a series of specialized "noses."

Barrows (1907) says:

I have found that *Drosophila ampelophila* (the vinegar fly) has a large saclike pit, which contains sense cones, situated in the end of the terminal (third) segment of the antennæ.

Gum on the antennæ did not prove satisfactory for abolishing sense of odors, nor could they be burnt off without considerable injury to the fly. He etherized some flies and cut the joint off with fine scissors and declares that the ether did not affect the results of the experiments with odors.

It, therefore, seems certain that the sense of smell is absent, or at least greatly reduced in flies that have lost the terminal joints of the antennæ.

He thinks that these flies when normal find their food wholly by smell.

When one antenna is lost and the other antenna is stimulated by food odor, circus movements are carried out in such a way as to prove that the fly orients normally by an unequal stimulation on the antennæ.

Kellogg (1907) informs us that the female silkworm moth protrudes a paired scent organ from the hindmost abdominal segment. A male moth with antennæ intact and with eyes blackened finds a female immediately and with just as much precision as when his eyes are not blackened. A male with the antennæ extirpated and eyes not blackened does not find the female unless by accident. Males with antennæ intact become greatly excited when a female is brought within several inches of them. If the excised scent glands are laid near the female from which they were taken, the males always neglect the near-by live female and go directly to the scent glands and try to copulate with them. A male with its left antenna removed, when within 3 or 4 inches of a female with protruded scent glands, becomes greatly excited and moves in circles around her to the right. A male with right antennæ off circles to the left.

Sherman (1909) discusses the sense of smell in insects without even giving any references or without performing any experiments.

He says: "The organs of smell are the antennæ." Insects that feed upon decaying matter find their food almost entirely by smell. When their antennæ are removed they are unable to find their food even though it is quite near and in full view. "This indicates that the sense of sight is defective and that of smell very acute."

To ascertain if the antennæ of honey bees, ants and hornets carry the olfactory organs, the author performed the following experiments. Worker bees with one antenna pulled off are much less pugnacious than are those with the antennæ intact, and they "pay less attention" to each other. They appear otherwise normal, except that their ability to communicate is considerably decreased. In observation cases they live only  $6\frac{3}{4}$  days while workers with unamputated antennæ live  $9\frac{1}{8}$  days under the same conditions. When tested with the three essential oils—peppermint, thyme and wintergreen—

their reaction time was 4.6 seconds, which is exactly double the reaction time when workers with unmutated antennæ are used.

Bees with one antenna pulled off and with 2 to 8 joints of the other one cut off never "pay any attention" to each other and very seldom are seen fighting, but are just as apt to fight a hive-mate as a stranger. The greater the number of joints severed, the less number of days they live and the more abnormal are they. On an average they live only 5 days and 11 hours. When tested with the three essential oils the following reaction times were obtained:

|                      | Seconds |                      | Seconds |
|----------------------|---------|----------------------|---------|
| 2 joints missing.... | 15      | 6 joints missing.... | 27      |
| 4 " " " "....        | 44      | 7 " " " "....        | 98      |
| 5 " " " "....        | 56      | 8 " " " "....        | 88      |

Bees with both antennæ pulled off live only 19 hours in observation cases and are completely abnormal in behavior. They always fail to respond to odors. When both antennæ are cut off at the bases, the bees live only 2 hours. They are also entirely abnormal and fail to respond to odors.

Bees with their antennæ covered with either shellac or celloidin do not live long and are quite abnormal. Bees with the antennæ covered with vaseline soon remove this substance and then behave normally again. Bees having the antennæ covered with liquid glue are abnormal until they remove the glue with their antenna cleaners. To prevent this removal the tarsi of the front legs including the antenna cleaners were burnt off with a red-hot needle. One-fourth of the bees so mutilated died within 12 hours, but the remainder appeared quite normal in every other way. On the second day the entire flagellum of each antenna was covered with liquid glue. These workers were quite abnormal and most of them did not live long. However, after gluing the flagella of many bees, 21 were finally obtained that were fairly normal and their reaction time to the three essential oils was 2.9 seconds, while the reaction time of the same odors for unmutated bees was 2.6 seconds. These 21 workers lived only 24 hours on an average. The odor from the glue did not affect these results.

Both antennæ of 95 workers were burnt off with a red-hot needle. These workers were quite abnormal and lived only 17 hours. Seven of them recovered sufficiently from the operation to respond to odors; while the others failed to respond. The reaction time of the 7 workers used to the three essential oils was 4 seconds.

Since the effect of the shock caused by mutilating the antennæ may have produced the abnormality in all the bees experimented with, 30 workers were immersed in water for 15 minutes. When removed

they appeared entirely lifeless and the antennae were pulled off at once. They revived and lived thereafter only 19 hours. When tested with odors they failed to respond and like all the other bees made completely abnormal, they scarcely moved when touched with a pencil.

Since bees whose antennae are mutilated after they become adults are abnormal, the antennae of 400 worker pupae were cut off. Several days later these workers emerged normally from their cells, but lived thereafter only 5 days.

The funiculi of 12 workers of *Formica* were cut off. These ants were then returned to a Fielde nest. They were slightly hostile to each other and to their uncut sisters. They failed to eat food and to catch flies, but their uncut sisters continually ate food and soon caught flies. The funiculi of 50 more workers of *Formica* were cut off. When returned to their cage, these ants were quite irritable and invariably attacked one another, and as a result several were killed.

The funiculi of 2 soldiers, 10 large workers and 7 small workers of *Camponotus* were cut off. When returned to their nest these ants attacked one another for three hours, then they became very inactive and responded to odors only slowly. The next day they were still quite inactive and "paid no attention" to anything, except when they came in contact with each other, they still fought one another. When tested with odors they failed to respond. At no time did they eat or drink.

The funiculi of 30 winged virgin females of *Formica* were cut off. When placed in experimental cases they were quite abnormal. Five of them failed to respond to odors and scarcely moved when touched with a pencil. These ants were discarded from the experiments. When tested with the three essential oils, the other 25 gave a reaction time of 4.38 seconds, while the reaction time for uncut sister females was 2.12 seconds. Confined in a Fielde nest, these mutilated ants lived only 19 hours.

The funiculi of 30 winged virgin females of *Formica* were covered with liquid glue. These ants were completely abnormal and five of them failed to respond to odors. When tested with the three essential oils the other 25 gave a reaction time of 5.78 seconds. They lived 6 days on an average.

The flagella of 25 *Vespa maculata* were cut off. In behavior these mutilated hornets were abnormal and lived only 1 day and 13 hours in observation cases. When tested with the three essential oils some of them responded promptly; some responded slowly, and a few failed to respond at all. All of those which failed to respond to

odors scarcely moved when touched with a pencil. These were discarded and the flagella of the others were cut off. The 25 used in these experiments gave a reaction time of 3.09 seconds which is 0.66 second greater than the same reaction time for normal hornets.

In conclusion under this head it is seen that about four-fifths of the writers cited advocate the view that the antennæ are the seat of the organs of olfaction. Most of these observers have not said whether the mutilated insects that they used were normal. The inactivity or state of rest of many of these specimens indicates abnormality. In regard to Miss Fielde's ants, only 40 per cent recovered from the effect of the shock and in all probability all of these were more or less abnormal. When the antennæ of ants, hornets and bees are mutilated in the slightest degree, as ascertained by the author, the insects are more or less abnormal. The results obtained by using any insect with mutilated antennæ are, therefore, in all probability more or less erroneous. Judging from the author's experiments there is no reason to assume the presence of the olfactory organs in the antennæ, because the differences in reaction times between the reaction times of the mutilated insects and those of uncut antennæ may be attributed to the abnormality of the insects which is probably always caused by the operations. At most it can be claimed only that the antennæ may assist in the receiving of odor stimuli.

Since the organs in the antennæ of ants, hornets and bees, and probably all insects, fail to receive most, if not all, odor stimuli, the true olfactory organs must be looked for elsewhere.

#### VARIOUS STRUCTURES ON THE ANTENNÆ AS OLFACTORY ORGANS

Before entering into a discussion of the antennal organs of insects, a brief description illustrated with drawings of the antennæ of the honey bee and their organs will first be given.

The antenna of the bee consists of two portions: the proximal part, called the scape, and the distal portion, the flagellum. Each portion is more or less cylindrical in shape. The scape consists of a single long, slender joint, while the flagellum consists of 11 short joints in the worker and queen and of 12 in the drone.

When an antenna is examined under the microscope with a strong transmitted light its surface is seen to be covered with small bright spots and also various kinds of hairs. In order not to overlook any of these peculiar structures, several pairs of these appendages from young bees just emerged from their cells were removed and perma-

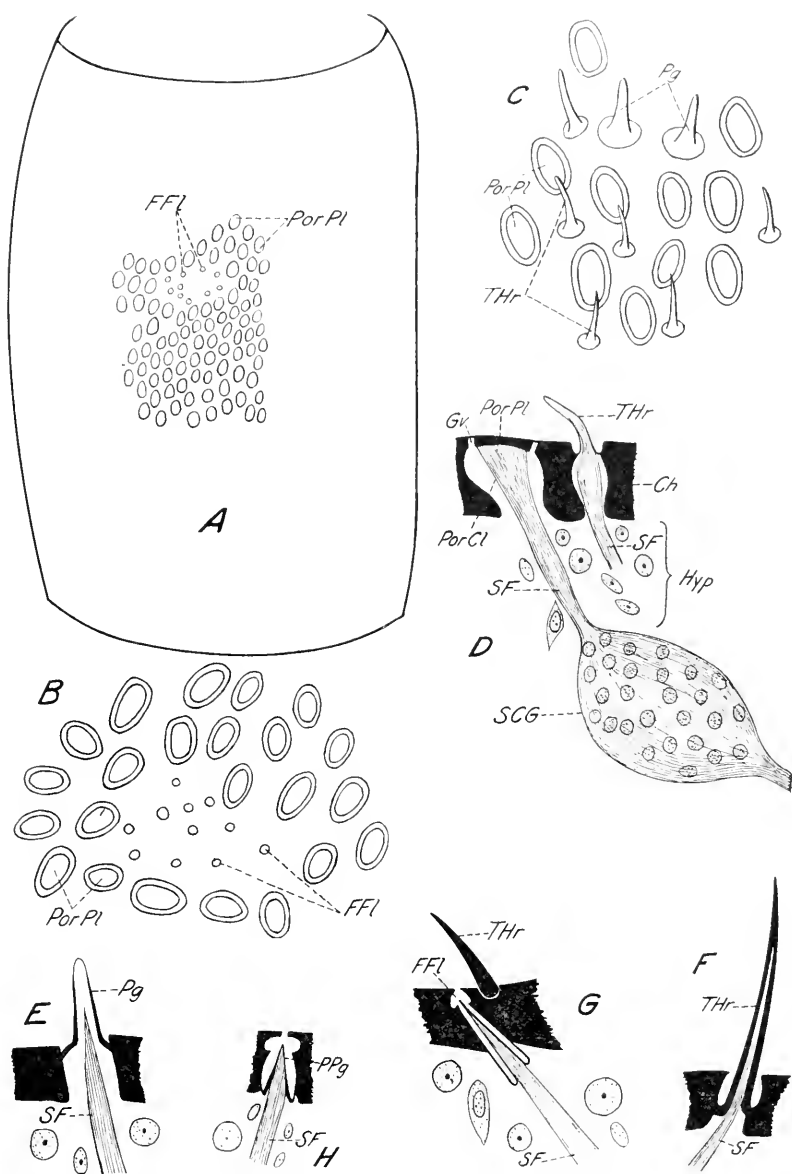

FIG. 1.—Antennal organs of the honey bee copied from Schenk. A, an antennal joint of a drone, showing a few of the many pore plates (*PorPl*) and a group of Forel's flasks (*FFl*),  $\times 150$ ; B, pore plates and Forel's flasks from a drone's antenna,  $\times 600$ ; C, pore plates (*PorPl*), pegs (*Pg*), and tactile hairs (*THr*) from a worker's antenna,  $\times 600$ ; D, internal anatomy of a pore plate and of a tactile hair; E, the same of a peg; F, the same of a tactile hair; G, the same of a Forel's flask; H, the internal anatomy of a pit peg. D-H,  $\times 600$ .

nently mounted. In these antennæ there is no dark pigment to obscure any of the antennal organs. To illustrate these various structures modified copies of Schenk's drawings (1903) are given (fig. 1).

Figure 1, A, shows the small bright spots (*PorPl*) on the drone antenna magnified 150 times. This drawing also shows still smaller bright spots (*PFl*) which are difficult to find. Formerly the larger bright spots were termed "pits" but later they were called "pore plates," "pore canals," and "sensilla placodea," while the smaller spots bear the names "Forel's flasks" and "sensilla ampullacea." In this discussion the former will be known as *pore plates* and the latter as *Forel's flasks*. Figure 1, B, represents these organs of the drone bee enlarged 600 diameters. Figure 1, C, shows the pore plates (*PorPl*) and two kinds of hairs from the antenna of a worker, enlarged 600 diameters. The stouter of these hairs (*Pg*) bear the names, "pegs," "clubs," and "sensilla basiconica," and the more slender ones (*THr*) "hairlike structures" and "sensilla trichodea." In this discussion the stout hairs are designated *pegs* and the slender ones *tactile hairs*. A fifth antennal organ whose external opening is not drawn by Schenk has the same superficial appearance as Forel's flasks and probably cannot be distinguished from them externally. These structures have been termed "pit pegs," "champagne-cork organs," and "sensilla cœloconica." They are here designated *pit pegs*.

Figure 1, D-H, show the internal anatomy of the five antennal sense organs. Figure 1, D, shows the structure of a pore plate and of a tactile hair. The chitin (*Ch*) is solid black, the sense fibers (*SF*) and sense cell ganglion (*SCG*) are represented by fine broken lines. Since the sense fibers in Schenk's drawing are defective and are not attached to the plate (*Pl*) as the writer has observed them many times in his sections, and as Schenk represents them in *Vcspa*, they are here drawn as they really exist. The plate is a hard and comparatively thick chitinous disc completely covering the pore canal (*PorCl*). However, at its margin there is a deep groove (*G $\sigma$* ) entirely surrounding the plate. To stimulate the sense fibers attached to the plate the odors must first pass through this hard chitinous plate.

Figure 1, E, shows a peg with its sense fibers running half-way to the tip of the hair. At its base the chitin is relatively thick while at the tip it is thin. If this structure is an olfactory organ, the odors must first pass through the thin chitin at the tip of the peg to stimulate the sense fibers. Figure 1, F, is a tactile hair. Figure 1, G and H, represent a Forel's flask and a pit peg respectively. Both of these

are nothing less than hairs inside of pits, and the only difference between them is the shape of the flask. If they are olfactory organs, odors must enter the small apertures and pass through the thin chitin at the tip of the hairs inside the pits, to stimulate the sense fibers.

In drones, the antennal organs are found on only the distal nine joints of the flagellum and in workers and in queens on the distal eight joints. According to Schenk, the pore plates are present on all of these joints, and while they are abundant on both the dorsal and ventral sides of the male antennæ, in the female antennæ nearly all of them occur on the dorsal side. On both antennæ of a male there are about 31,000 and on those of a female only about 4,000; however, those of the female are considerably larger. Pegs are entirely absent from the drone antennæ, while they are abundant on those of workers and of queens. As a rule they are at the distal end of the joint on the dorsal side. The male antennæ are always devoid of tactile hairs whereas those of the female have many. Forel's flasks and pit pegs are moderately numerous in both sexes, but slightly less abundant in the female antennæ.

Some of these antennal organs, or at least modifications of them are present in the antennæ of all species of insects with probably one or two exceptions. In butterflies and moths pore plates are entirely absent and pegs are almost wanting. However, the place of the pegs seems to be taken by end rods, which are very similar in structure but are more club-shaped. Butterflies and moths also have bristle-like tactile hairs.

Pore plates, pegs, Forel's flasks, pit pegs and end rods have all been considered as olfactory organs by various authors, who, in trying to prove their views, assert that odors can pass through the hard chitin of these organs so that the nerve fibers inside may be stimulated. While these authors declare that this is possible in insects, they acknowledge that it would be impossible in the higher animals.

Erichson (1847), according to Hicks (1859c), first observed the pore plates and hairs on the antennæ of insects. He considered the pore plates as olfactory organs for two reasons: (1) He thought that the numerous hairs on the antennæ protect and keep these plates moist, so that odors can pass through them, and (2) they are more numerous in those insects whose smell is acute.

Burmeister (1848) describes the pits found on the antennæ of lamellicorn beetles. These are a variety of the pit pegs, and he attributes an olfactory function to them.

Vogt (1851), according to Wonfor (1874), discovered that the antennæ are covered with minute pores which are apparently filled

with fine hairs. He thinks that these structures perform a function combining those of smell and touch.

Bergmann and Leuckart (1852) say that when one brings a drop of ether on the tip of a needle near the head of an insect it moves and strokes its antennæ. They speak of many pits on the antennæ; from the base of these pits arise small papillæ which they regard as olfactory organs.

Leydig (1860, 1886) made a thorough investigation of the pore plates discovered by Erichson. He found these pore plates not only in the antennæ of most insects but also discovered that they are modified into peculiar, peglike organs in the remaining insects, and in the crustaceans and myriapods. Leydig regarded these organs of questionable function as olfactory. In 1860 he thought that the palpi have a function similar to that of the antennæ.

Lespés (1858) compares the pore plates to the ears of higher animals and denies their olfactory office.

Hicks (1859b and c) thinks that the pore plates are cavities filled with fluid, closed in from the outer air by a delicate membrane to which a nerve is attached. He regards the pore plates as auditory organs and says:

If we assign an olfactory function to these organs, one difficulty presents itself, viz: that for the odorous particles to affect the nerve they must reach it through a membrane and a stratum of fluid.

Landois (1868) experimented with the stag beetle (*Lucanus cervus*). He does not doubt that this beetle can smell, for if exposed to the fumes of sulphuric acid, or ammonia or to tobacco smoke it draws in its antennæ quickly. If the ends of the antennæ are removed it still draws in the remainder of these appendages with the same rapidity as when the antennæ are intact. He found two kinds of sense hairs on the antennæ of this insect and pits filled with small hairs. He thinks, however, that olfaction is performed by none of these organs.

Grimm (1869) describes three kinds of hairs and a pitlike organ on the antennæ of beetles but does not regard any of these as an olfactory apparatus. He put a beetle with entire antennæ into a box which had a glass cover and an opening at the bottom covered with thin cloth. After this beetle had become quiet he put a piece of dung to the opening. The beetle at once came to the opening and tried to tear the cloth. Later he cut off its antennæ and repeated the experiment, and the beetle came to the opening as before. By repeating these experiments many times he concluded that the antennæ of

beetles do not function as smelling organs. Also he infers, like Leydig, that there may be some olfactory rods or pegs on the palpi of this beetle.

Gegenbaur (1870) briefly discusses the antennal organs described by Erichson, Burmeister and Leydig but fails to express his own opinion concerning their function.

Lowne (1870) believes that the olfactory apparatus of the blow-fly is located in the third antennal joint. This joint is remarkably dilated and is covered with minute openings which communicate with little sacs in the interior.

Müller (1871) found stiff hairs and pore plates on the flagella of the antennæ of a female bee, but only pore plates on those of the male bee. He thinks that the pore plates are olfactory organs and that male bees have a better olfactory sense than the females for the following reasons: (1) A male bee has one more joint in the flagellum; (2) all of these joints are longer, and (3) wider, and (4) the pore plates are so close together that they crowd out the stiff hairs.

Claus (1872) thinks that many insects have a well developed olfactory sense and that the surface of the antennæ is the seat of the sense of smell, basing this conclusion upon the work of Erichson and that of Leydig.

Chadima (1873), after examining the hairlike structures on the antennæ and palpi of crustaceans, insects and myriapods, which Leydig (1860) regarded as most probably olfactory organs, says that the smelling organs of arthropods have not yet been found. He states that none of these hairs is perforated at its tip. He thinks investigators will have more success in solving this problem if they look on the olfactory sense as being connected with the breathing apparatus.

Forel (1874) counted five different kinds of organs on the antennæ of ants—(1) olfactory knobs or pegs, (2) tactile hairs, (3) pore plates, (4) Forel's flasks and (5) pit pegs. Forel (1902) judging from the works of Hicks, Leydig, Hauser, Kräpelin and himself remarks that all the reputed olfactory structures of the antennæ are modified pore canals bearing hairs. They come under three chief forms—pore plates, olfactory knobs, and olfactory hairs. At times the last two can hardly be distinguished from one another. Chitin, even if very thin, always covers the end of the nerve. Forel's flasks and pit pegs have no relation to smell because they are lacking in the insects with acute smell (wasps) and are present in great abundance in insects (bees) with poor sense of smell. The same author (1908, pp. 95 and 96) still regards the pit pegs and Forel's flasks as a

physiological enigma. They are generally absent, but are present in ants and aphidids, are quite abundant in the domestic bee, are present but not abundant in bumble bees, and are absent in wasps; nevertheless, he thinks they have nothing to do with olfaction. In dragonflies and cicadas the antennæ are rudimentary and the sense of smell is poor. The organs of smell of insects are in general situated in the antennæ, especially in their swollen or perfoliate parts where the antennal nerve ramifies. "These 'horns,' these 'ears' form, therefore, a famous nose in spite of Wolff and Graber." Thus Forel believes that the antennæ are the olfactory organs, yet he does not state what particular antennal organs receive the olfactory stimuli.

Bertè (1877) states that none of the antennal organs in fleas is for olfaction.

Lubbock (1877) discusses the antennal organs but does not venture to suggest their functions.

According to Vom Rath (1888), Lubbock (1883) found the same structures on the antennæ as did Forel (1874), although the details are somewhat different. Neither Forel nor Lubbock ventures to ascribe an olfactory function to any one of the five antennal organs, but by their many experiments, particularly on ants, both are thoroughly convinced that the antennæ carry the olfactory apparatus.

Graber (1878) describes a pitlike sense organ in the antennæ of flies. This was long before described by Leydig as an olfactory apparatus, but Graber regards it as an auditory organ.

Mayer (1878, 1879) regards the pitlike organs or pore plates as being most probably olfactory in function.

Reichenbach (1879) thinks that the small pits filled with hairlike structures are the olfactory organs in insects.

Hauser (1880) studied the behavior of various insects before and after the removal of the antennæ. When the antennæ were cut off many individuals soon became sick and died, although some of them lived thereafter for many days. In insects with their antennæ dipped in melted paraffin, the behavior was similar to that of those with the antennæ amputated. He placed 12 individuals (beetles) *Philonthus cuneus* R. one at a time in an inverted beaker whose bottom was removed. He slowly placed a clean glass rod in front of the head and the insect gave no response. He then repeated the operation with a glass rod dipped in carbolic acid. When this was 4 inches away the insect was much affected, it lifted and moved its head in different directions and made quick forward movements with its antennæ. When the glass rod was brought nearer it moved away quickly and

drew its antennæ through its mouth. The reaction to turpentine and acetic acid was more violent. Next he cut off the antennæ. On the second day after the operation he repeated the experiments, but the insects failed to respond to any one of these three strong odors. After the operation the beetles ate with a greater appetite and some of them lived more than two months thereafter. From these experiments he concludes that the beetles lost the olfactory sense by the removal of the antennæ.

Experiments with species of several other genera gave the same results but those with beetles of the genera *Carabus*, *Melolontha*, and *Silpha* were less satisfactory. These never completely failed to respond to strong-smelling substances. If they are exposed for a long time to the odors the insects deprived of their antennæ become restless and walk away from the glass rod, yet all the movements are less energetic. The entire reaction is indefinite and weakened. Experiments with Hemiptera gave a still less favorable result. After the loss of the antennæ these insects reacted almost as well as they did with their antennæ intact.

Hauser performed the following experiments to ascertain the value of the antennæ in the search for food. He placed beetles (*Silpha*) in a large box whose bottom was covered with moss. In one corner of the box he put a small glass with a small opening, the glass containing foul meat. As long as the insects possessed their antennæ they regularly found the meat in the glass after some time, while after the removal of the antennæ they never came in contact with it. Similar experiments were performed with flies of three genera. A vessel containing spoiled meat was placed on a table by an open window. Soon several flies came to the meat. Then he closed the window and cut off the antennæ at the third joint. Thereafter not one of these flies came in contact with this meat.

Hauser next ascertained the value of the antennæ to the male in finding the females. Male and female beetles and butterflies were placed in large boxes. As long as they were normal in every respect they mated freely, but when the antennæ were cut off they copulated only occasionally.

Hauser, who worked extensively and thoroughly on the antennæ of insects of all orders, found many differences in the various orders but among different Hymenoptera the differences in distribution and structure of the antennal organs are comparatively slight. According to him, *Vespa* (a wasp) possesses about three times as many pegs as does the honey bee, and for this reason *Vespa* has better olfactory

perception. *Formica* (an ant) has far more pegs than pore plates, contrary to the rule in hymenopterous insects. In conclusion Hauser asserts that in almost all insects the olfactory organ consists of (1) a large nerve arising from the cephalic ganglion which runs out into the antenna, (2) a recipient end apparatus which represents rod cells modified from hypodermal cells with which the fibers of those nerves are connected, (3) a supporting and accessory apparatus which is formed by the pore plates and pegs filled with a serous fluid. When both pore plates and pegs are present they both function in smelling according to their number; when one of these organs is absent then the other one functions entirely as an olfactory receptor.

Kräpelin (1883), according to Schenk (1903), considers the pore plates and pegs as smelling organs and translating from Vom Rath (1888) Kräpelin thinks that the olfactory organ is also located in the palpi.

Schiemenz (1883) regards the pegs as touch organs, while the pore plates and Forel's flasks probably serve as olfactory organs.

Sazepin (1884) worked chiefly on the antennæ of myriapods, but he also spent some time in working out the anatomy of the antennæ of *Vespa*. By comparing the anatomy of the myriapods' antennæ and with that of *Vespa* he found that as a whole there is a great similarity, but while the olfactory pegs in *Vespa* are closed at their tip, they are open in what he calls the olfactory pegs in myriapods.

Witlaczil (1885) worked on the antennæ of certain bugs. Since their antennal pits, called olfactory pits by Hauser, are covered by a membrane he thinks that they can scarcely be called olfactory organs.

Vom Rath (1887, 1888), like most authors on this subject, regards the olfactory sense as located in the sense pegs of the antennæ and probably also in the pore plates. By making a comparative study of all the antennal organs in arthropods, Vom Rath (1895) found a great similarity in the structure of each set of organs. The sense pegs are not by any means confined solely to the antennæ but are found on all the mouth parts, in the mouth cavity, and even over the entire body. It is possible that many pegs serve for the reception of the stimuli of weak odors from a distant object and others for the olfactory perception of those nearer. It may be that the pegs of each kind, and also the pore plates, are especially responsive to certain kinds of odors. He believes that the pegs on the palpi possess an olfactory function and possibly for odors close at hand. Moreover, these pegs elsewhere may have the same function.

Ruland (1888), who made a thorough comparative anatomical study of insect antennæ, contends that only such hair structures as those which are perforated at the tips can be sensitive to chemical stimuli. Pegs are found in all orders of insects and, since myriapods and crustaceans possess similar structures, these organs may be considered as the chief form of olfactory organs in the arthropods. Ruland regards the pit pegs and Forel's flasks found in most insects as simple pit pegs, while the compound pits, as seen in the antennæ of flies and butterflies, he calls compound pit pegs. He believes that all three sets of these organs are organs for the reception of stimuli from certain olfactory substances. To determine whether all of the hair structures are perforated at their tips, he put the antennæ into boiling caustic potash. After such treatment he observed that they were all open at the end. In the investigations made by the author it was learned that caustic potash within a short time not only destroys all of the internal tissue but it soon dissolves thin chitin. All who have studied these structures before and since 1888 assert that these hairlike organs are tipped with very thin chitin through which the odorous particles must pass. In the observations made by the author these structures in the antennæ of the honey bee have not shown a single hair which is open in the slightest degree at the tip and it is probable that in Ruland's treatment the caustic potash dissolved the thin chitin at the tip.

Nagel (1892, 1894, 1909, the views set forth in the first reference being cited by various authors,) states that, in his opinion, the antennæ are generally the olfactory organs of insects—not, however, without exception. That insects, after amputation of the antennæ, seem incapable of perceiving odors is not sufficient proof that the antennæ are olfactory organs. He declares (1894) that organs with thick chitinous walls cannot function in smelling, but he thinks that the olfactory pegs, being tipped with thin chitin, are capable of receiving olfactory stimuli. He asserts that these olfactory pegs are found on other parts of the body besides the antennæ. He (1909) does not doubt that in many insects the palpi may assist in smelling. In the antennæ of a May beetle there are four different kinds of pitlike organs (varieties of pit pegs), all of which may be olfactory in function. In the Hymenoptera the antennæ are the only seat for their highly developed olfactory sense. In some Hymenoptera both pore plates and pegs, while in others only the pore plates, function in smelling. In ants the pegs and knee-shaped bristles probably serve this purpose; in Lepidoptera the pit pegs function for smelling when the

insect flies, the end rods serving such a purpose while the insect is resting; in Diptera the pit pegs, similar to those of butterflies, are the olfactory organs. Nagel repeated most of Hauser's experiments and seems to be convinced that the antennæ are almost always, if not always, the seat of the organs of olfaction. When one or more of these organs are absent the next best, histologically considered, must perform the olfactory work; and when all the antennal organs are wanting, as in *Ephemera vulgata*, a pseudoneuropteran, he imagines that the insect cannot smell.

Dahlgren and Kepner (1908) regard the knob-shaped, pitlike antennal organs of *Necrophorus* as the olfactory organs. They found glandlike cells beneath the hypodermis which they believe to be associated with these pits and perhaps aid in receiving odor stimuli.

Nearly all of the foregoing observers have overlooked the sense organ found in the second antennal joint of insects. This is called Johnston's organ. In *Cespa* the upper end, or the nerve rod, of the organ penetrates the articulating chitin between the second and third joints and comes to the surface. From its structure an olfactory sense might be attributed to it. According to Child (1894a and b), who experimented extensively with mosquitoes, this organ serves as a combined touch and auditory apparatus and has nothing to do with olfaction.

Lubbock (1899) says:

Forel and I have shown that in the bee the sense of smell is by no means very highly developed. Yet their antenna is one of those most highly organized. It possesses—besides 200 cones [pegs], which may probably serve for smell—as many as 20,000 pits [pore plates]; and it would certainly seem unlikely that an organization so exceptionally rich should solely serve for a sense so slightly developed.

From this fact and his numerous experiments Lubbock regards the antennæ as the seat of the organs of olfaction, yet he does not commit himself as to the particular antennal organs which receive the odor stimuli.

Börner (1902) states that only a few of the hair structures on the antennæ of *Collembola* may be regarded as olfactory organs.

Schenk (1903) claims that the fact that the males of *Apidae* (bees) do not possess any pegs does not argue against the view that these structures are olfactory organs for (1) the pit pegs, which certainly have an olfactory function, are common to the antennæ of males, queens and workers, and (2) in hunting for the females the olfactory sense appears to be of second place to sight. In the summary of his observations on *Lepidoptera* Schenk asserts that the pit pegs function

as smelling organs, because they are more highly developed and more advantageously distributed on the antennæ in the males so that they may be of the greatest use in scenting the females. The end pegs also aid in olfaction, particularly when the insect is resting. He does not think that the pore plates in Hymenoptera have an olfactory use, and he regards this view as based on insufficient data. Olfaction in the Vespidae (wasps) is accomplished by the pegs, because the pit pegs are almost absent, while in the bees the pegs and pit pegs both are olfactory in use; but since the male bees do not have these pegs, the sense of smell is entirely performed by the pit pegs.

Röhler (1905) made a special study of the antennal organs in a grasshopper, (*Tryp. ralis*) *Acridella nasuta* L. On the antennæ he found only three kinds of organs, viz: bristles, pegs and pit pegs. Of these three he regards only the pit pegs as olfactory in function, and the females have only about two-thirds as many of them as have the males. This additional number of pit pegs greatly aids the males in finding the females.

Cottreau (1905) discusses the sense of smell of insects in a popular way, without performing any experiments or citing any references. He says that the olfactory organs are the pits and papillæ, distributed abundantly on the antennæ and without doubt in certain regions on the mouth parts.

In discussing olfaction and antennal sense organs of insects Berlese (1906) seems to infer that there can be no doubt that the antennæ are really the seat of the smelling organs.

In a comprehensive study of the morphology of the chitinous sense organs of *Dytiscus marginalis*, a water beetle, Hochreuther (1912) finds seven different kinds of organs. Of these seven only the hollow pit pegs (hohle Grubenkegel) are probably olfactory in function. They not only occur on the antennæ and mouth parts, but a few are found on the thorax and perhaps a few on the coxæ of the first two pairs of legs.

#### CAUDAL STYLES ("ABDOMINAL ANTENNÆ") AS SEAT OF OLFACTORY ORGANS

Packard (1870) discovered that the caudal styles of the female *Chrysopila* (a fly) possess a peculiar sense organ. On the posterior edge of the upper side of each style there is a single, large, round sac with quite regular edges. Its diameter is equal to one-third of the length of the style. Dense, fine hairs project inward from its edge, and the bottom of this shallow pit is a clear, transparent membrane devoid of hairs. Since this same insect possesses no antennal organs

Packard believes that this structure is an olfactory apparatus. He calls this a "simple nose," while in the caudal styles of the cockroach there is a "compound nose."

#### ORGANS ON BASES OF WINGS AND ON LEGS AS OLFACTORY ORGANS

While examining the organs on the halteres of flies, Hicks (1857) discovered on the bases of the wings peculiar structures which he called vesicles, arranged in a single row extending some little distance up the vein on both sides of the wing, but principally on the upper side. By examining insects of other orders he ascertained that these organs are not confined to the Diptera. He believes that they are found in all insects, and they were present in all specimens examined by him. They exist on both sides of the wing, but chiefly on the upper side of the base on the subcostal vein and in the Hemiptera on the costal vein. Those on the hind wing are generally larger in size and greater in number.

In Moths they are very apparent, being greatest in the Noctuæ [Noctuidæ] and Bombycidæ. There are about 100 vesicles on the upper surface of the posterior wing, and half that number beneath, besides some few on the nervures [veins]. In the butterfly they are smaller, but arranged in more definite groups, about three in number. In Coleoptera and Neuroptera they are arranged in long rows along the subcostal nerve; they are more apparent in Coleoptera than in Neuroptera. In the Hymenoptera, for instance the bee, they are found in a rounded group of about forty on each side.

Are they organs of smell, as suggested by Mr. Purkiss? As the olfactory organ has never yet been decided on, it seems to me not improbable that they be the organs of that sense; for, first, it is not likely that they should be the organ of hearing, as they are in constant motion, and situated near the source of the hum of the wings, so that other sounds would be drowned, 2ndly, it is not necessary that the power of smell should be in the head. It is situated in the commencement of the air passages in the upper animals probably because the current of air or water passing the olfactory nerves is there most powerful; but in the spiracle-breathing insects the greatest currents are in the neighborhood of the wing, and near the greatest thoracic spiracle. The motion of the halteres also permits a greater exposure to odors floating in the air.

He claims that the organs on the halteres and on the base of the wings are similar in structure and probably have the same function, that of smell. He was able to trace a nerve to each group of organs, the one going to the hind wing being the larger.

Hicks (1859a) presented a second paper concerning these organs in which he asserts:

I may here repeat that each of these structures consists of very thin and transparent, hemispherical or more nearly spherical projections from the

cuticular surface, beneath which the wall of the nervure is deficient, so as to allow a free communication with its interior; these organs are arranged in rows on the halteres and in variously shaped groups in the wings.

He examined one or more species of about two dozen genera representing all of the insect orders. He observed these organs in the honey bee, in *Vespa*, and in all other species examined by him except *Corysus* [*Corisus*], the bedbug (*Cimex lectularius*), an apterous beetle, and the flea (*Pulex irritans*). Usually these structures consist of two groups on the upper, and one scattered group on the under side of the subcostal vein, amounting in *Ophion* to from 200 to 300 above, and perhaps 100 beneath, with a smaller group at the end of the vein. In the Diptera these vesicles are found both on the wings and halteres. In the Coleoptera they are highly developed and occur in numerous groups on the subcostal vein, mostly at the widest part, but are also scattered along it to the joint of the wing. In *Carabus* (a beetle) they are found on veins other than the subcostal. In many beetles the vesicle is overarched by a hair, which probably protects the organ. He could distinguish no differences in the sexes except that the vesicles were slightly larger in the females, due to their greater size. These organs are most perfectly developed in the Diptera, slightly less perfectly developed in the Coleoptera, rather less so in the Lepidoptera, only slightly developed in the Neuroptera, scarcely at all in the Orthoptera, and only a trace of them exists in the Hemiptera. He gives several drawings, but they represent only the superficial appearances.

Hicks (1860) discovered these same vesicles on the trochanter and femur, chiefly on the former, in all the insects he examined. In *Formica rufa* (an ant) these structures are numerous and exist both on the trochanter and femur. A few small groups of these vesicles are also present on the proximal end of the tibia in this ant. In the honey bee these organs are not so abundant on the legs but are located at the same places as on the ant. The vesicles on the legs, like those on the wings, consist of a thin, delicate membrane

stretching over, and closing in from the air, a tubular aperture in the chitin-layer of the part. This aperture may be circular or oval, the tube varying in length according to the thickness of the integument, curved as in the Hornet, or forming a globular cavity as in *Silpha*. The delicate membrane which covers over this aperture is generally level, sometimes leaving a ridge or a minute papilla in its center.

Hicks gives drawings showing the disposition of these vesicles or pores on the wings and legs of many of the species examined. He saw nerves running to all of these organs and gives a very good idea

concerning their structure, although since our modern technique of making stained sections was entirely unknown in his time we should not expect his drawings to represent the finer anatomy of these pores. He used the following technique:

After cutting off the wing and washing it well in water or spirits of wine, and draining off the major part by blotting paper, I immerse it in spirits of turpentine for a week or two, after which it is placed in Canada balsam between glass in the normal way, taking care not to heat it, as that renders the nerve too transparent. In those parts which are too dark for observation, I have been enabled to render them colorless by Chlorine.

In regard to smell in insects and the function of the pores on the legs Hicks says:

The delicacy with which odours are perceived by many insects argues an olfactory apparatus of considerable perfection; and it seems to me not impossible that these latter named organs [those on the legs] may be in some way connected with the sense of smell, or perhaps with some sense not to be found in the Vertebrata.

To summarize Hicks' three papers, he discovered these pores on the halteres and on the bases of the wings of all Diptera examined; on the bases of all four wings of the four-winged tribes; on the trochanter and femur of all insects, and occasionally on the tibia. He examined many species representing various insect orders and found these pores even on the lower insects, such as the earwig. In such wingless insects as the worker and soldier ants, he infers that these pores are much more abundant on the legs than they are on these appendages in the winged insects. Hicks suggested an olfactory function for all of these pores, whether on the legs or wings, but he performed no experiments of any kind.

Weinland (1890) and several others have made a special study of the halteres or balancers of flies and the sense organs on the bases of these appendages. Weinland distinguishes four kinds of structures on the halteres, all of which are similar in most respects and differ only in minor details. Their internal anatomy is similar to that of Hicks' vesicles. Of these four structures Weinland calls only one of them Hicks' papillæ, and neither he nor anyone else except Hicks and Bolles Lee (1885) has ever attributed an olfactory sense to any of the structures on the balancers.

Guenther (1901) studied the nerve endings found in butterfly wings. He spent a short time on the anatomy of Hicks' vesicles but failed to recognize them as the ones which Hicks first described in 1857. Guenther calls them sense domes (*Sinneskuppeln*). He describes the external appearance of them as being light spots whose

thin chitin is arched in the shape of a dome. Each light spot is surrounded by a dark, chitinous ring. The internal anatomy consists of a sense cell, sense fiber, and a flasklike cavity with its chitinous cone. All of these parts are almost identical to those in Hymenoptera described by the author but Guenther failed to see the sense fiber join the aperture at the bottom of the flask. Thus his drawing shows a thin chitinous arch or dome which completely closes the external end of the flask, the sense fiber running up against this chitinous dome. If he had prepared more sections and used light colored stains such as safrain and not dark stains like hämatoxylin, he could certainly have seen the sense fiber join the aperture in the dome. Guenther tries to liken these pores to the membrane canals of Vom Rath. A similar dome-shaped membrane was found in the antennæ of lamellicorn beetles by Hauser, Kräpelin, Vom Rath, and others, but these bear a little hair at their center. Hauser attributes an olfactory function to such structures, but Guenther shares the opinion with Vom Rath and Graber that they have an auditory rôle.

Janet (1904) found porelike sense organs in large numbers in all the ants that he examined. These pores are either widely separated or, more frequently, united into groups. They occur on the labial palpi and on the tongue, and there are some on the pharynx, besides many on the legs. Janet recognizes those on the legs as the same vesicles or organs that Hicks describes in 1860. In a wasp (*Vespa*) and an ant (*Formica*) their disposition is almost identical with that in the honey bee. Janet's drawings of the superficial aspects of these pores are very similar to those of the author but on account of the small size of the specimens he seems to have had trouble in understanding their internal anatomy. According to him, all the pores, whether on the mouth parts or legs, have a similar structure, and they resemble the structure of the olfactory pores found in the honey bee; however, there are a few slight differences. He calls the chitinous cone an umbel, which is always separated from the surrounding chitin by a chamber. This chamber communicates with the exterior by means of the pore. The sense fiber, or his manubrium, runs into the umbel, and he thinks that it spreads out over the inner surface of the umbel and does not open into the chamber. Thus the umbel forms a thin layer of chitin which separates the end of the sense fiber from the external air. The rôle of these organs is evidently to permit the end of the nerve to become distributed on a surface relatively large and separated from the air only by a thin layer of permeable chitin. Janet fails to give drawings that show the sense fibers run-

ning all the way to the umbel and apparently has not seen the way in which the nerves actually end in the umbels.

Janet (1907) describes and gives a drawing of one of these same organs that he found near the articulation of the wing of a queen ant. Its morphology is the same as described above. Thus in ants, according to Janet, we see that Hicks' vesicles are not only found on the legs, but also near the wing articulations and probably also on the mouth parts. According to their anatomy, as Janet describes it, these organs function as some kind of a chemical sense and in fact are as suitable to perceive olfactory stimuli as are the antennal organs, if not more suitable.

Wesché (1904) remarks that a certain bot-fly has a highly developed sense of smell, equal to that of many mammals. This fly has large antennæ containing sense organs that are larger than those in some other flies; some of these organs are known to function as a keen olfactory sense.

I think that where the antennæ are not particularly sensitive, the palpi have this structure to compensate. We thus see that the palpi, like the antennæ, can bear organs of three senses—touch, taste, and smell; but I do not think that any one palpus has more than two of these senses developed at the same time.

Besides making such broad statements concerning the senses of insects, the same writer describes and gives drawings of some sense organs that he thinks entirely new. Some of these he found on the legs, which are without doubt Hicks' vesicles. He observed these organs in *Icsipa* and in many Diptera and his description of their superficial appearance fits what has been seen by the author. Wesché remarks that these organs are possibly auditory or for some unknown sense; however, he says nothing about their internal anatomy or any literature relating to them.

Freiling (1909) spent a short time studying the anatomy of Hicks' vesicles as found in the wings of butterflies. While Guenther found these sense domes (Sinneskuppeln) in great numbers, irregularly scattered on the veins near the base of butterfly wings, Freiling regards them as regularly distributed in the same location. The superficial appearance, as he has drawn it, is similar to that of the bee. He shows a large bipolar sense cell with its sense fiber running to the apparent opening in these organs but he thinks that the sense fiber ends [clublike] just beneath the apparent aperture. He worked three weeks trying to get good sections of these organs and succeeded in getting only one specimen from which he obtained fairly good sections. Freiling gives only one drawing each of the external and the

internal structure of these organs, and the latter is drawn diagrammatically. In this he fails to show the chitinous cone, and the end of the sense fiber is represented as separated from the exterior by the thin layer, forming the dome. On this incorrect interpretation of the anatomy, he, like Guenther, speculates on their probable function and concludes that these sense domes may serve as some kind of a barometric device or as an apparatus for measuring the force of the air against the wing.

Berlese (1909, pp. 678-684) calls all the dome-shaped organs of insects "sensilli campaniformi o papilliformi." The campaniform type is found on the mandibles, antennæ, legs and wings. Their domes never project above the general surface of the surrounding chitin. The papilliform type occurs only on the halteres. Here the domes project above the surface of the chitin. In schematic drawings he shows how the domes may have been derived from a portion of the chitin originally not arched. Berlese regards the function of these organs as unknown.

While studying the morphology of the chordotonal organs in the honey bee and ants, Schön (1911) found two rows of small cones on the proximal end of each tibia. A sense cell lies just beneath each cone and the peripheral end of the sense fiber runs into the cone. These sense cells connect with the chordotonal organ located in the middle and distal end of the tibia. Schön has certainly mistaken Hicks' vesicles for cones, because the external appearance of these vesicles often resembles cones when observed without the cylindrical tibia being properly rotated. These organs always lie near the edge of the tibia, and when one looks down upon them their apertures look like cones, but when the tibia is rotated slightly, so that they lie on the median line of the tibia, the optical illusion becomes evident.

Hochreuther (1912) describes and gives drawings of the dome-shaped organs (kuppelförmigen Organe) in a manner somewhat similar to that of Janet. Each organ is located at the bottom of a chitinous flask, the mouth of which communicates with the exterior. Instead of the peripheral end of the sense fiber coming into direct contact with the air in the flask, it apparently stops just beneath the chitinous dome. No true chitinous cone is present, but his terminal strand (Terminalstrang) resembles it somewhat in general appearance. He finds a few of these dome-shaped organs on the epicranium near the margin of the eyes, 11 on the first and second joints of the antennæ, a few on the dorsal side of the labrum, very few on the dorsal side of the mandibles, several on the maxille, about 18 on the first four joints of the first legs, about 10 on the first three joints of

the second legs, and a few on the trochanter of the third legs. He evidently has not examined the wings. Thus according to Hochreuther these organs are rather widely distributed. Since the per-

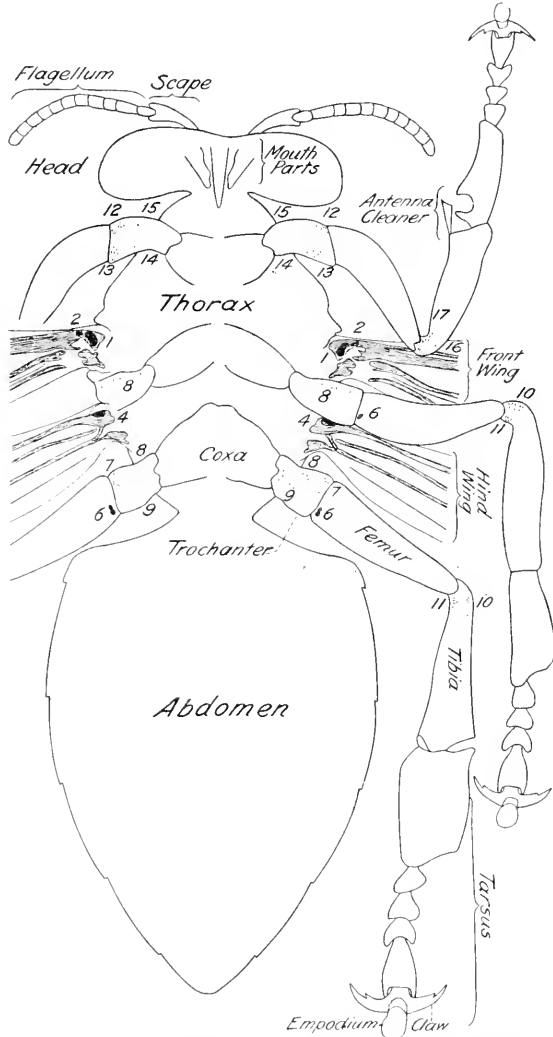

FIG. 2.--Diagram of ventral view of a worker bee, showing the location of the different groups of olfactory pores as indicated by the numbers.

ipheral ends of the sense fibers do not come into contact with the outside air, but connect with the tops of the domes, he suggests that they receive some kind of mechanical stimuli, although he performed no experiments to determine their function.

The following results were obtained by the author. The disposition of Hicks' vesicles (called olfactory pores by the author) is best understood by referring to the numbers in figures 2, 3 and 4 of the

FIG. 3.—Diagram of dorsal view of a worker bee, showing the location of the different groups of olfactory pores as indicated by the numbers.

honey bee. Groups 1 to 5 lie on the bases of the wings as indicated by the numbers 1 to 5. Groups 6 to 18 lie on the legs. Group 19 to 21 lie on the sting of the worker and queen (fig. 4). The same organs are found on the mouth parts of all the hymenopterous insects

examined, but they have not yet been thoroughly studied. The antennæ of the honey bee and probably the antennæ of all Hymenoptera do not carry any of the organs first described by Hicks.

The olfactory pores in other hymenopterous insects are similar in position to those of the honey bee. Among the 29 species examined, these pores vary much in the number of groups and in the number of pores contained in the individual groups. As a rule, the lower the insect the fewer the groups and more isolated are the pores. *Cimber*, regarded as the lowest hymenopteron, has the least number of groups of all the species examined, but it stands fourth in regard to the number of isolated pores. Its total number of pores is larger

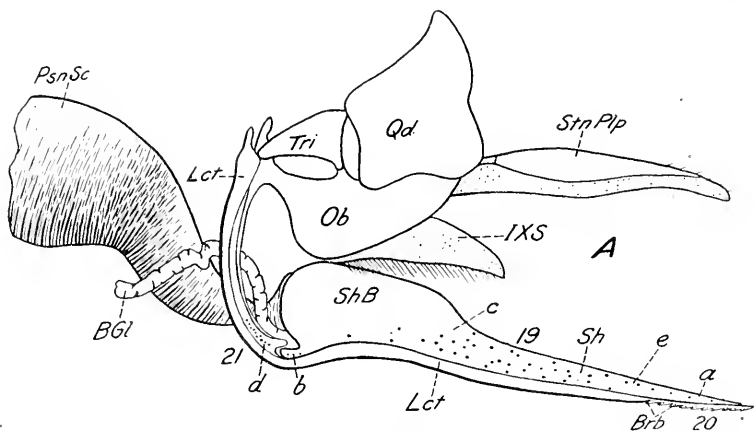

FIG. 4.—Diagram of lateral view of a worker bee's sting and its accessory parts, showing the location of the olfactory pores as indicated by the numbers.

than that of many of the higher forms. Among ants the variations are also great. For the legs of ants the number of pores varies from 211 to 356 and for the winged ants the total number varies from 463 to 1,090. The smallest specimen among the ants and the second smallest one of all the Hymenoptera examined is a female with 463 pores as the lowest number. The drone honey bee with 2,608 pores has the highest number. The smallest specimen examined is a wasp with 688 pores. The following table including 6 of the 29 species examined will illustrate the variations in the number of olfactory pores as found on the three pairs of legs and the two pairs of wings. The letters "F," "M," "H" and "G" stand for front, middle, hind and grand, in the order named. The "Total" means all the pores found on all 6 legs, and the "G. total" means all the pores found on all 6 legs and all 4 wings combined.

TABLE I  
Average number of olfactory pores on the legs and wings of Hymenoptera

| Apidae.                     |                        | Bombidae.              |                        | Vespidæ.                    |                         | Formicidæ.                           |                         |                        |                        | Braconidæ.                         |                        | Cimbicidæ.                     |                        |                         |    |    |   |    |    |   |    |    |   |    |    |   |     |    |            |

In size the olfactory pores vary much. Those of an ant vary more in size than do those of the hornet or honey bee. The pores on the wings are always much smaller than are those on the legs and they vary less in size. In proportion to the sizes of an ant and of a worker honey bee, the pores of the ant are much larger.

Under the microscope with transmitted light the olfactory pores appear as bright spots. At the first glance they resemble hair sockets (fig. 5, *PorApHr*) from which the hairs have been pulled, but after

FIG. 5.—Group 6 of the olfactory pores from the hind leg of a worker bee, showing the external appearance, x 700.

a closer examination a striking difference is usually seen. Each bright spot is surrounded by a dark line, the pore wall (figs. 5 and 6, *PorW*). Outside this line the chitin (fig. 5, *PorB*) may be light or dark in color, but inside the line the chitin (figs. 5 and 6, *ChL*) is almost transparent, and at the center there is an opening, the pore aperture (figs. 5 and 6, *PorAp*).

The olfactory pores consist of inverted flasks in the chitin and of spindlelike sense cells lying beneath the mouths of the flasks (fig. 6). About two-thirds of the space at the bottom of the flask is occupied by a hollow chitinous cone (fig. 6, *Con*) which is not separated from

the surrounding chitin, but only stains less deeply. In a typical olfactory pore the neck (NkFl) of the flask is wide and the mouth (Mf) is flaring. The sense fiber (SF) of the sense cell (SC) pierces the bottom of the cone and enters the round, oblong, or slitlike pore aperture (Por.Ap). The nerve fiber (NF) soon runs to a nerve. It is thus seen that the cytoplasm (Cyt) in the peripheral end of the sense fiber comes in direct contact with the air containing odorous particles and that odors do not have to pass through a hard membrane in order to stimulate the sense cells as is claimed for the antennal organs.

To determine the function of these pores the wings, legs and stings of many worker honey bees were mutilated. The behavior of the mutilated bees was carefully studied, and they were tested with odors

FIG. 6.—Cross section of a typical olfactory pore with its sense cell (SC) from the tibia of the hind leg of a worker bee, x 700.

in the same manner as were unmutated ones. The stings of 100 workers were pulled out. These bees lived 30 hours on an average. Twenty of them were tested with odors. They responded only slightly more slowly than unmutated bees. The wings of 28 workers were pulled off. When tested with odors, these bees responded one-eighth as rapidly as normal bees. The bases of the wings of 20 workers were covered with liquid glue. When tested, these bees responded also one-eighth as rapidly as unmutated ones. The pores on the legs of 20 workers were covered with a mixture of beeswax and vaseline. When tested, these bees responded two-fifths as rapidly as unmutated workers. The wings were pulled off and the pores on the legs of 20 workers were covered with the beeswax-vaseline mixture. When tested with odors, these workers responded one-twelfth as rapidly as unmutated workers. All of the workers with mutilated wings and legs lived just as long in the observation cases as did unmutated workers, and they were absolutely normal

in all respects except that they reacted to odors more slowly. Controls proved that the odors themselves from the glue and beeswax-vaseline mixture did not affect the reaction times.

The preceding experiments were repeated by using ants and hornets with mutilated wings and legs. When tested with the odors from the oil of peppermint, oil of thyme, oil of wintergreen, honey and comb, leaves and stems of pennyroyal, and formic acid from other ants, four deálated females of *Formica* gave a reaction time of 2.89 seconds. The reaction time for winged females of the same species is 2.45 seconds. The niches from which wings of these four females arises were examined. In seven of the eight niches, pores were seen.

All four wings of each of 25 virgin females of *Formica* were pulled off. When tested with the above six odors, these ants gave a reaction time of 2.85 seconds. After an examination it was found that 62 per cent of the detached wings had broken off just beyond the groups of pores, thus the pores on only 38 per cent of the wings were lost. When the wings are shed naturally only 21 per cent of the pores are lost, while 79 per cent are not prevented from functioning, because the wings devoid of pores always break off at a weak place in the chitin just distal to the groups of pores. Furthermore, sections through the stubs of the wings of deálated females show that the sense cells are normal.

The wings of 7 males of *Formica* were pulled off. When tested with the six odors, these ants gave a reaction time of 3.50 seconds, while the reaction time for the same ants before the wings were pulled off is 2.63 seconds. They were normal in all respects other than their slowness in responding to odors. Only 8 per cent of the pores belonging to the wings were left intact while 92 per cent were pulled off with the wings.

The bases of the wings of 25 winged females of *Formica* were covered with liquid glue and the pores on the legs were covered with the beeswax-vaseline mixture. Confined singly these ants were not able to remove the glue, but they did remove much of the vaseline and smeared some of it over their spiracles, which certainly accounts for their short lives. When tested, they gave a reaction time of 5.21 seconds, which is slightly more than twice the reaction time for their unmutilated sister females.

• When tested, 25 deálated females of *Camponotus* gave a reaction time of 3.25 seconds. Their wing niches were filled with liquid glue thus covering the pores on the stubs of the wings, and the pores

on the legs were covered with the beeswax-vaseline mixture. These females now appeared normal in all respects other than their slowness in responding to odors. When tested, they gave a reaction time of 7.94 seconds, which is more than twice the reaction time obtained before using the glue and vaseline.

The wings of 25 males of *Camponotus* were pulled off. These ants appeared normal in all respects except their slowness in responding to odors. When tested, they gave a reaction time of 3.49 seconds, which is one and a fourth times the reaction time of unmutilated males. Only 12 per cent of the pores on the wings were left intact.

The wings of 21 workers of *Vespula maculata* were pulled off. These hornets appeared normal in all respects other than their slowness in responding to odors. When tested with the three essential oils, they gave a reaction time of 6.35 seconds, which is almost three times the reaction time for sister hornets with wings intact. Only 22 per cent of the pores on the wings were left intact.

#### OLFACTORY ORGANS ON THE APPENDAGES AND STERNUM OF SPIDERS

In 1878 Bertkau noticed some slitlike cuticular organs on the legs of spiders. Since that date five other observers, including the present writer, have studied these structures. They are called lyriform organs on account of their shape.

The author (1911) made a special study of the morphology and physiology of the lyriform organs of spiders. He used in his studies 39 species representing 27 of the 38 families. These organs in spiders exist both as isolated slits and as groups containing several slits, and their position is relatively constant. The groups are located at the distal end of each joint of the legs, pedipalpi, chelicera (mouth parts), pedicel, and spinnerets. They exist on both sides of the fore-going appendages and as a rule each joint of the legs and pedipalps possesses the following number of groups: Coxa 1, trochanter 3, femur 2, patella 3, tibia 3, metatarsus 1, and occasionally the tarsus 1; each cheliceron usually has 4, each pedicel 2, and only occasionally is a group present on one of the spinnerets. The isolated slits not only occur irregularly scattered on the joints of all the above-named appendages, but also on the remaining mouth parts, on the sternum, and a few on the ventral side of the abdomen. Thus it is seen that the disposition of the lyriform organs is similar to that of Hicks' vesicles; however, the vesicles are situated at the proximal instead of the distal ends of the joints and less seldom exist as isolated struc-

ures irregularly distributed, as are the isolated slits. A few of Hicks' vesicles exist on the mouth parts but none is found on the sternum and abdomen, except those in the sting, which might be compared in position to the lyriform organs on the spinnerets of spiders. Since spiders have no wings, possibly all the slits on the mouth parts, sternum, pedicle, and the ones on the abdomen exclusive of those on the spinnerets, replace all the pores that exist on the wings of insects.

A great difference in the number of groups and isolated slits was found in the different species. The spiders that hunt for their food and use no webs in capturing their prey, without exception have the most slits, while those that live in caves and catch their food entirely by means of webs have the least number. The common cobweb spider (*Theridium tepidariorum*) catches its prey wholly by webs; it does not live in caves and may be considered as intermediate between hunting spiders with highly developed lyriform organs and cave spiders with degenerated lyriform organs. By counting all the slits on the surface of this cobweb spider, we find that an average spider possesses 1,770 slits, whereas considering an average worker bee, we have already seen that it possesses 2,270 pores. As stated by the other observers, lyriform organs have now been found in 7 of the 9 orders belonging to the Arachnida.

A lyriform organ is composed usually of several single slits which lie side by side and more or less parallel with each other. This group of slits is generally surrounded by a border, produced by a difference in pigmentation, which gives the lyre shape to the organ. Inside the border the pigmentation is usually much lighter than outside; hence a group appears as a light spot, while the superficial appearance of a slit reminds one of a long, slightly bent spindle that has an aperture either at the center or nearer one end than the other. A cross section of a slit shows that the aperture passes entirely through the cuticula and unites with the sense fiber of a large spindlelike sense cell lying at the base of the thick hypodermis. Thus a cross section of a slit with its sense fiber may be likened to a greatly flattened funnel. The innervation of a lyriform organ is identical with that of a group of olfactory pores, except that in the former the sense fibers unite with the base of the apertures, whereas in the latter the sense fibers connect with the top of the apertures.

So far as the writer knows, structures similar to lyriform organs and Hicks' pores have never been looked for in crustaceans. It is very probable, however, that this class of arthropods possesses some kind of organs that take the place of lyriform organs and Hicks' pores.

While experimenting with odors, it was found that spiders possess a true olfactory sense. Many individuals of two species representing two widely separated genera were used. They responded not only to five different essential oils, which are sometimes regarded as irritants, but also to both fresh and decayed buttercup flowers, decayed snails, squash bugs, and Phalangids. The usual reaction is to move away from the odor, but they also quickly moved their pedipalpi, chelicera and legs, and very often rubbed their legs and other appendages. The average reaction time of a ground spider (*Lycosa lepida*) to oils of peppermint, thyme and wintergreen was 9 seconds and for a jumping spider (*Phidippus purpuratus*) 4.6 seconds, while for the worker bee the same average is only 2.6 seconds. The differences in reaction time may be explained by the fact that *Lycosa* is rather sluggish, *Phidippus* is very active, while the bee is extremely lively. However, as a worker bee possesses 500 pores more than a spider and since it responds about twice as quickly it would appear that its sense of smell is more highly developed.

All the lyriform organs (single slits not included) on the legs, pedipalpi, chelicera, mouth parts, and sternum were carefully varnished with yellow vaseline. The following day they were tested with the five oils—peppermint, thyme, wintergreen, clove and bergamot. Thus it was ascertained that they responded nine times more slowly after varnishing than before.

Hindle and Merriman (1912) proved experimentally that Haller's organ is olfactory in function and that it is a means by which ticks are able to recognize their hosts. In *Haemaphysalis punctata* this organ consists of a minute cavity, containing sensory hairs, and is associated with a specially modified region of the hypodermis. In ticks (Acarina) it is always located on the external dorsal surface of the tarsus of the first pair of legs. Hansen (1893) found a few scattered lyriform organs in acarinids which may also aid in receiving odor stimuli.

#### SUMMARY OF AUTHOR'S EXPERIMENTS

The following table is a tabulated summary of the author's experiments with spiders and Hymenoptera to determine the location of the olfactory organs. The odors used for the spiders are those from the essential oils of peppermint, thyme, wintergreen, clove, and bergamot. The "three odors" used for the Hymenoptera are those from oil of peppermint, oil of thyme, and oil of wintergreen. The

TABLE II

Summary of author's experiments with spiders and Hymenoptera to determine the location of the olfactory organs

| Species.           | Experiment.  | Average reaction time. |                | No. of individuals tested. | Average length of life in captivity. |       |

"six odors" used for the ants and hornets are those from oil of peppermint, oil of thyme, oil of wintergreen, honey and comb, leaves and stems of pennyroyal, and formic acid. The "six odors" used for the honey bees are the same as those used for ants and hornets, except pollen was employed instead of formic acid.

The preceding table shows the following: (1) When the pedipalpi (slightly comparable to the antennæ of insects) of spiders are pulled off, the arachnids are normal in behavior and the reaction time is practically the same as when unamutilated individuals are

used. (2) But when the antennæ of Hymenoptera are mutilated in the slightest degree, the insects are abnormal, and the reaction times are slower than when unamputated individuals are used, although it is quite possible that the slower reaction times are caused by the abnormal behavior of the insects rather than due to the theory that some of the olfactory organs are prevented from functioning. (3) When the maxillæ of spiders are pulled off, no abnormal behavior results, but the reverse is true for the honey bee. In both cases the reaction time is slightly slower. (4) When the mouth parts of honey bees are mutilated, the insects are abnormal and the reaction times are slightly increased, which may be due to the abnormality of the insects, or to the view that the pores on these appendages are prevented from functioning, or to both of these conditions combined. (5) When the wings are pulled off artificially, most of the pores on these appendages are lost and the reaction times are considerably increased. (6) When the pores on the wings are covered with glue the reaction times are much increased. (7) When most of the pores on the legs are covered with vaseline, the reaction times are greatly increased. (8) When either spiders or Hymenoptera are so mutilated that most of the olfactory pores are prevented from functioning, the reaction times are increased many times, and the mutilated individuals used are absolutely normal in all respects other than their ability to smell.

#### DISCUSSION

The following criticisms concerning the physiological experiments performed with the antennæ of various insects may be offered. Most of the previous observers have studied the behavior of the insects investigated in captivity for only a short time, while the remainder have paid no attention at all to the behavior of their unamputated insects. They cut off either a few joints of both antennæ, or these entire appendages, or varnished them with paraffin, rubber, etc. When a few joints are severed the sense of smell is apparently weakened. This is true for bees also as ascertained by the author. When both antennæ are amputated or varnished the insects, as a rule, fail to respond to substances which normally affect the olfactory sense. They generally fail to respond to odors held near them and fail to find food in captivity, and do not return to putrid meat and dead bodies when removed from such food. Males so mutilated do not, as a rule, seek females and show no responses when females are placed near them. Such experiments were seriously criticised until Hauser in 1880 presented his apparently conclusive results. Many

of the insects on which he experimented with the antennæ amputated became sick and soon died. Most of them failed to respond when the antennæ were mutilated, although *Carabus*, *Melolontha*, and *Silpha* responded slightly, while all the Hemiptera that he used responded almost as well with their antennæ off as they did with them intact. Only 40 per cent of the ants from which Miss Fielde cut the antennæ recovered from the effect of the shock. Not one of these observers has studied the behavior of the species under observation sufficiently to know exactly how long they live in captivity with their antennæ either intact or mutilated. No one, except Miss Fielde, has kept a record of the death of the mutilated and normal insects accurate enough so that one might know what percentage died from the operation. To cut off some other appendage or even the lower part of the head, as Forel did, is not a fair test, because such operations seldom expose sense cells and never any nerve equal in size to that of the antennæ, unless one pulls off the wings. When the wings are pulled off the large nerve is severed between the masses of sense cells and thorax, and the sense cells are not exposed to the air, as they are when antennæ are cut off. Even if the antennæ are cut through the scape, the large masses of sense cells belonging to Johnston's organs are severed. When the lower part of the head or the tarsi are cut off, as Forel did, no nerves are exposed to the air except ends of small nerves. From the foregoing it is only reasonable to assume that when the antennæ of any insect are injured in the least degree, the insect is no longer normal and if it fails to respond to odors placed near it, this negative response may be caused by the injury.

The following criticisms based on a consideration of the morphology of the antennæ may also be offered. In the honey bee the pore plates can scarcely be considered as olfactory organs, because the drone has almost eight times as many as the queen, and responds to the odors presented in slightly more than one-half the time. It is true that those of the queen are considerably larger, but even on this basis the reaction times are not comparable. The pegs may be entirely eliminated as olfactory organs, because they are absent in the drone, but are abundant in the worker and the queen. Drones, queens and workers have about the same number of Forel's flasks and pit legs. Schenk's view that the pegs receive odor stimuli in the queens and workers, while Forel's flasks and the pit pegs function in this way in the drones is inconsistent, because if the latter two structures function for such a purpose in the drones why should

they not also in the females? Since these two structures are few in number and many times smaller than the pegs, we cannot compare them physiologically. Thus it is seen that not one of these antennal organs of the honey bee offers a solution for the ratios obtained with the use of the various odors. If the reaction time of each caste of the honey bee is compared with the total number of olfactory pores a consistent inverse ratio is obtained. A drone has 2,600 pores and responds in 2.9 seconds; a worker possesses 2,200 pores and responds in 3.4 seconds and a queen has 1,800 pores and responds in 4.9 seconds.

Pore plates are not the olfactory apparatus in all insects, because they are entirely absent in the Lepidoptera. The pegs cannot be the olfactory organs in all insects, for they are absent in many male bees and almost wanting in Lepidoptera, although possibly the end rods in butterflies and moths are homologous. According to Vom Rath, pegs are found not only on the antennæ and mouth parts but also all over the body, and Nagel found them elsewhere than on the antennæ. If the pegs are the olfactory organs and if insects with amputated antennæ are normal, then why do not such insects respond positively at least slightly to odors instead of negatively, as most observers claim?

It is certain that spiders can smell, yet they have no antennæ nor any organs that may be compared to the antennal organs of insects. Hence, this is another argument against the antennæ as being organs of smell. All insects either have antennal organs like those described for the bee, or modifications of them, yet no two authors who have studied them have agreed concerning their function. Such chaos can be replaced by facts, only when the behavior of the insects investigated is thoroughly studied and when experiments are performed in ways other than on the antennæ alone. Then it will be realized that the antennæ can no longer be regarded even as a possible seat of the sense of smell in insects.

In conclusion, it seems that the organs called the olfactory pores by the author are the true olfactory apparatus in Hymenoptera and possibly in all insects and that the antennæ play no part in receiving odor stimuli.

# ARCHEOLOGY OF THE LOWER MIMBRES VALLEY, NEW MEXICO

By J. WALTER FEWKES

(WITH EIGHT PLATES)

## INTRODUCTION

Evidences of the existence of a prehistoric population in the Lower Mimbres Valley, New Mexico, have been accumulating for many years, but there is little definite knowledge of its culture and kinship. It is taken for granted, by some writers, that the ancient people of this valley lived in habitations resembling the well-known terraced dwellings called pueblos, many of which are still inhabited along the Rio Grande; but this theory presupposes that there was a close likeness in the prehistoric architectural remains of northern and southern New Mexico. It may be said that while there were many likenesses in their culture, the prehistoric inhabitants of these two regions possessed striking differences, notably in their architecture, their mortuary customs, and the symbolic ornamentation of their pottery.

As the former inhabitants of the Mimbres Valley have left no known descendants of pure blood, and as there is a scarcity of historical records, we must rely on a study of archeological remains to extend our knowledge of the subject. Much data of this kind has already been lost, for while from time to time numerous instructive relics of this ancient culture have been found, most of these objects have been treated as "curios" and given away to be carried out of the country, and thus lost to science. Some of these relics belong to a type that it is difficult to duplicate. For instance, it is particularly to be regretted that the numerous votive offerings to water gods, including fossil bones, found when the "sacred spring" at Faywood near the Mimbres was cleaned out, have not been studied and described by some competent archeologist. The arrowheads, lance-points, and "cloud-blowers" from this spring are particularly fine examples, the most important objects of the collection being now in the cabinet of Mrs. A. R. Graham of Chicago.<sup>1</sup>

---

<sup>1</sup>In a letter to Professor W. H. Holmes, published in his paper, "Flint Implements and Fossil Remains from a Sulphur Spring at Afton, Indian Terri-

The valley of the Mimbres has never been regarded as favorable to archeological studies, but has practically been overlooked, possibly because of the more attractive fields in the regions to the north and west, so that only very meager accounts have been published.<sup>1</sup>

The present article, which is a preliminary report on an archeological excursion into this valley in May and June, 1914, is an effort to add to existing knowledge of the archeology of the valley. During this reconnaissance the author obtained by excavation and purchase a collection of prehistoric objects which have added desirable exhibition material to the collections in the U. S. National Museum.<sup>2</sup>

#### HISTORICAL

The recorded history of the inhabitants of the Mimbres is brief. One of the earliest descriptions of the valley, in English, is found in Bartlett's "Personal Narrative," published in 1854. In his account of a trip to the copper mines at the present Santa Rita, Bartlett records seeing a herd of about twenty black-tailed deer, turkeys and other game birds, antelopes, bears, and fine trout in the streams. He

---

tory." Mr. A. R. Graham gives an instructive account of cleaning out the Faywood Hot Springs where he found the following relics: (1) parts of skulls and bones of several human beings; (2) over fifty spearheads and arrowheads of every shape and style of workmanship, the spearheads being valuable for their size and symmetry; (3) nine large warclubs made of stone; (4) a large variety of teeth of animals as well as large bones of extinct animals; (5) the most interesting relics are ten stone pipes from four to seven inches in length; (6) flint hatchet and a stone hammer, together with stones worn flat from use; beads made of vegetable seed and bird bones; part of two Indian bows with which was found a quiver in which was quite a bunch of long, coarse black hair that was soon lost after being dried.—*Amer. Anthropol.*, n. s., vol. 4, pp. 126, 127.

<sup>1</sup>The Santa Rita mines early attracted the conquistadors looking for gold, and were worked in ancient times by the Spaniards, the ores obtained finding an outlet along a road down the valley to the city of Chihuahua. The prehistoric people also mined native Mimbres copper, and probably obtained from these mines and from those in Cook's Range, the native copper from which were made the hawk-bells sometimes found in Arizona and New Mexico. From these localities also were derived fragments of float copper often found in Southwestern ruins and commonly ascribed to localities in Mexico. From here came also a form of primitive stone mauls used in early days of the working of the mines.

<sup>2</sup>The National Museum had nothing from the Lower Mimbres before this addition, although it has a few specimens, without zoic designs, from Fort Bayard, in the Upper Mimbres. The latter are figured by Dr. Hough, *Bull.* 87, U. S. National Museum.

says very little, however, about antiquities, although he passed through a region where there are still several mounds indicating ruins. Bartlett writes (*op. cit.*, vol. 1, p. 218):

On April 29, hearing that there were traces of an ancient Indian settlement about half a mile distant, Dr. Webb went over to examine it, while we were getting ready to move. He found a good deal of broken pottery, all of fine texture. Some of it bore traces of red, black, and brown colors. He also found a stone mortar about eight inches in diameter. I have since understood that this was the seat of one of the earliest Spanish missions; but it was abandoned more than a century ago, and no traces remain but a few heaps of crumbling adobes, which mark the site of its dwellings.

This ruin was situated near the Rio Grande, twenty-three miles from Mule Spring, on the road to the Mimbres. Bartlett does not tell us how he learned that this was an early mission site, but from the pottery it is evident that it was an "ancient Indian settlement."

After having examined the configuration of the country through which Bartlett passed, and having compared it with statements in his description, the present writer thinks that Bartlett camped on May 1, 1853, near the Oldtown ruin and that the place then bore the name Pachetehu. This camp was nineteen [eighteen?] miles from Cow Spring and thirteen miles from the copper mines.

Bartlett records that he found, near his camp, "several old Indian encampments with their wigwams standing and about them fragments of pottery." Although not very definite, these references might apply either to the Oldtown ruin and some others a few miles up the river, or to more modern Apache dwellings.

Mr. F. S. Dellenbaugh claims that Coronado, in 1540, passed through the valley of the Mimbres on his way to Cibola, and that this place was somewhere in this region, instead of at Zuñi, as taught by Bandelier and others. The present writer recognizes that the question of the route of Coronado is one for historical experts to answer, but believes that new facts regarding the ruins in the Mimbres may have a bearing upon this question and are desirable. While it can no longer be said in opposition to Dellenbaugh's theory that there are no ruins in the valley between Deming and the Mexican border, we have not yet been able to discover whether the ruins here described were or were not inhabited in 1540.

The fragmentary notice of the ruins in the Upper Mimbres and Silver City region by Bandelier is one of the best thus far published, although he denies the existence of ruins now known in the great

stretch of desert from Deming to the Mexican boundary. Regarding the ruins on the Upper Mimbres, Bandelier writes:<sup>1</sup>

Toward this center of drainage the aboriginal villages on the Rio Mimbres have gravitated as far south nearly as the flow of water is now permanent. They are very abundant on both sides of the stream, wherever the high overhanging plateaux have left any habitable and tillable space; they do not seem to extend east as far as Cook's Range, but have penetrated into the Sierra Mimbres farther north, as far as twenty miles from the river eastward. . . . The total number of ruins scattered as far north as Hincks' Ranch on a stretch of about thirty miles along the Mimbres in the valley proper, I estimate at about sixty. . . . I have not seen a village whose population I should estimate at over one hundred, and the majority contained ten. They were built of rubble in mud or adobe mortar, the walls usually thin, with overhangs, and a fireplace in the corner, formed by a recess bulging out of a wall. Toward the lower end of the permanent water course, the ruins are said to be somewhat extensive.

Professor U. Francis Duff, in an article on the "Ruins of the Mimbres Valley,"<sup>2</sup> adds a number of new sites to those mentioned above and contributes important additions to our knowledge of the prehistoric culture of the valley.

Dr. Walter Hough, who compiled from Bandelier and Duff, and made use of unpublished information furnished by Professor De Lashmutt and others, enumerates twenty-seven ruins in the Silver City and Mimbres region to which he assigns the numbers 147-174. Many more ruins<sup>3</sup> might have been included in this list, but it is not the author's purpose, at this time, to mention individual pueblo sites but rather to call attention to the evidences of ruins in the Lower Mimbres Valley as an introduction to the study of pottery there collected. The ruin from which the majority of the bowls here considered were obtained does not appear to have been mentioned by Bandelier, Duff, or Hough.

The last-mentioned author makes the following reference to figures on the pottery from the Mimbres region: "The decoration is mainly geometric. From the Mimbres he [Professor De Lashmutt] has seen a realistic design resembling a grasshopper, and from Fort Bayard another representing a four-legged creature. Mrs. Owen has a

<sup>2</sup> American Antiquarian, vol. 24, p. 397, 1902.

<sup>3</sup> Bandelier (*op. cit.*, p. 357) speaks of sixty ruins in a small section thirty miles along the river.

specimen from Fort Bayard bearing what is described as a 'fish design.'"<sup>1</sup> Dr. Hough likewise points out that

pottery from some sites [ruins] is also different from that of any other [Pueblo] region and is affiliated, in some respects, with that of the Casas Grandes, in Chihuahua which lies in the low foot-hills of Sierra Madre. This is especially true in reference to fragments of yellow ware found here [the Florida Mountains] which in both form and color of decoration is manifestly like that of Casas Grandes.<sup>2</sup>

The latest and thus far the most important contribution to our knowledge of the prehistoric people of the Mimbres we owe to Mr. C. L. Webster, who has published several articles on the antiquities of the Upper Mimbres, in "The Archæological Bulletin." He has made known several new village sites along the valley and has mentioned, for the first time, details regarding Mimbres ruins and the objects found in them. Practically nothing has thus far been recorded on the antiquities of the region immediately about Deming, nor of those south of that important railroad center to the Mexican border.

In an article on "Some Burial Customs Practiced by the Ancient People of the Southwest,"<sup>3</sup> Mr. Webster describes and figures a human burial on the Lower Mimbres not far from the "Military Post," situated near Oldtown. It was found in the plain some distance from any indications of prehistoric settlement. He says:

An exploration of it [a burial] revealed that originally a circular excavation, perhaps three feet in diameter and slightly more in depth, had been made in the ground; and afterwards the body placed at the bottom of this excavation in a sitting posture with the knees somewhat drawn up and arms to the side, and then a very large earthen olla, of a reddish color, was set over it, bottom side up, thus protecting it from the earth which was afterwards thrown in, filling up the excavation.

Mr. Webster shows that the Mimbres aborigines did not always bury their dead in a contracted or seated posture. He speaks also of intramural or house burials in the valley of Rio Sapillo, a tributary of the Upper Gila, not far from the source of the Mimbres. In this region he dug down in one of the central rooms of a ruin about three feet below the surface, where he says (p. 73):

Near the bottom of this excavation hard red clay was encountered, which on opening up proved to contain the well-preserved skeleton of an adult person

<sup>2</sup> Bandler found that Mimbres pottery resembles that of several regions, including Casas Grandes.

<sup>3</sup> The Archæological Bulletin, vol. 3, No. 3, p. 70.

which had been placed at length on its back with arms at its side. Over the face of this one [human burial] had been placed a rather large shallow dish, through the bottom of which a hole about the size of a five cent piece, or a little larger, had been carefully drilled. This hole was so located as to occupy a position between the eyes when placed over the face. This body was resting on a bed of red clay like that which had covered it. Near the first body was a second body which had been buried in exactly the same way, and had a similar perforated dish over its face. Under this first or upper tier of bodies a second tier of bodies was discovered which had been buried exactly the same way as the upper tier—each one resting separate and alone, though near together, each one tightly enveloped in stiff red clay.

All the vessels placed over the faces showed the action of fire, and it was plain to be seen they had once been used in cooking. . . . The method practised here was to first spread down a layer of red plastic clay, then lay the body upon it, place the perforated dish over the face and finally plaster all with a covering of the same clay. This same method was followed in every case observed.

#### SITES OF RUINS IN THE LOWER MIMBRES VALLEY

The portion of the Sierra Madre plateau called Lower Mimbres, or Antelope Valley, extends from where the Mimbres sinks below the surface at Oldtown to Lake Palomas in Mexico, twenty-five miles south of Deming. According to some writers this region has no prehistoric ruins, but several of the beautiful specimens described and figured in the present article came from this valley, and there are doubtless many others, equally instructive, still awaiting the spade of the archeologist. The purest form of the Mimbres prehistoric culture is found in the lower or southern part of this plain, but it extends into the hills far up the Mimbres almost to its source.

The plateau on which the prehistoric Mimbres culture developed is geographically well marked, and distinguished from other regions of the Southwest geographically and biologically, facts reflected in human culture. The cultural gateway is open to migrations from the south rather than from the east, north, or west.

The evidences drawn from the poor preservation of the walls of the ruins, and the paucity of historical references to them, instead of indicating absence of a prehistoric population suggest the existence of a very ancient culture that had been replaced by wandering Apache tribes years before the advent of the Spaniards. Chronologically the prehistoric people belongs to an older epoch than the Pueblo, and its culture resembles that which antedated the true Pueblos.<sup>1</sup>

---

<sup>1</sup> During the author's stay in Deming he was much indebted to Dr. S. D. Swope for many kindnesses, among which was an opportunity to study his valuable collection, now in the high school of that city. He was also greatly

The ruins here considered do not belong to the same type as those of the Lower Gila and Salt, although they may be contemporaneous with them, and may have been inhabited at the same time as those on the Casas Grandes River in northern Chihuahua. Not regarded as belonging to the same series of ruins as those on the Upper Gila and Salt rivers, they are not designated numerically with them.

Although the indications of an ancient prehistoric occupancy of the Mimbres are so numerous, they are so indistinct and have been so little studied that any attempt here to include all of them would be premature. Remains of human occupancy occur in the plain about Deming, and can be traced northward along the river east and west into the mountains, and south into Mexico.

The author has observed many evidences of former settlements along the Upper Mimbres which have not yet been recorded. The indications are, as a rule, inconspicuous, appearing on the surface of the ground in the form of rows of stones or bases of house walls, fragments of pottery, and broken stone implements, such as metates and manos. These sites are commonly called "Indian graves," skeletons often having been excavated from the enclosures outlined by former house walls. There are also evidences of prehistoric ditches at certain points along the Mimbres, showing that the ancients irrigated their small farms.

No attempt is made here to consider all the ruins of the Mimbres or of the Antelope plain in the immediate neighborhood of Deming, but only those that have been visited, mainly ruins from which the objects here described were obtained.

Although few of the walls of the ancient buildings rise high above ground, they can be readily traced in several places. From remains that were examined it appears that the walls were sometimes built of stone laid in mortar and plastered on the inside, or of adobe strengthened at the base with stones and supported by logs, a few of which have been found in place upright. No differentiation of sacred and secular rooms was noticed, and no room could be identified as belonging to the type called kiva. The floors of the rooms were made of "caleche," hardened by having been tramped down; the fireplace was placed in one corner, on the floor, and the entrance to the room was probably at one side. To all intents and purposes these dwellings were probably not unlike those fragile wattle-walled structures found

---

aided by Mr. E. D. Osborn and several other citizens, and takes this opportunity to thank all who rendered assistance in his studies. The photographs reproduced in the present paper were made by Mr. Osborn.

very generally throughout the prehistoric Southwest, and supposed to antedate the communal dwellings or pueblos of northern New Mexico.

The two aboriginal sites in the Mimbres Valley that have yielded the majority of the specimens here figured and described are the Old-town ruin and the Osborn ruin, a small village site twelve miles south of Deming and four miles west of the Florida Mountains. There are some differences in general appearance and variations in the minor archeological objects from these two localities, but it is supposed that specimens from both indicate a closely related, if not identical, culture area.

About a year ago Mr. E. D. Osborn, of Deming, who had commenced excavation in these ruins,<sup>1</sup> obtained from them a considerable collection of pottery and other objects. His letters on the subject and his photographs of the pottery, sent to the Bureau of American Ethnology, first led the author to visit southern New Mexico to investigate the archeology of the Mimbres.

#### VILLAGE SITE NEAR OSBORN RANCH<sup>2</sup>

A few extracts from Mr. Osborn's letters regarding this site form a fitting introduction to a description of the sites and the objects from them:

At the present time [December 8, 1913] the nearest permanent water to this place [site of the cemetery] is either the Palomas Lake in Mexico, twenty-five miles south, or thirty miles north, where the Mimbres River sinks into the earth. . . . This supposed Pueblo site is situated upon a low sandy ridge which at this point makes a right-angle bend, one part running south and the other west from the angle. The top and sides of the ridge, also the "flat" enclosed between the areas of the ridge, to the extent of about an acre, is littered all over with fragments, charcoal and debris containing bones to the depth of from one to three feet. There are also a great many broken metates and grinding stones. . . . In digging on top of this ridge, near the angle, we occasionally found what appeared to have been adobe wall foundations, but not sufficiently large to determine the size or shape of any building. In digging on the ridge a few stone implements were found, including one fine stone axe, stone paint pots and mortars, and a few arrowheads, also two bone awls and a few shell beads and bracelets, the last all broken. The only article of wood was the stump of a large cedar post full of knots, badly decayed; it had been burned off two or three inches below the surface of the ground. The cemetery was found on the inner slope of the angle facing the southwest. . . . In a

<sup>1</sup> Specimens were also found by Mr. Osborn at the Byron Ranch ruin, at the Black Mountain site, and elsewhere.

<sup>2</sup> This is the ruin called Osborn ruin in subsequent descriptions.

large proportion of cases the body was placed upon its back, feet drawn up against the body, knees higher than the head; sometimes the head was face up and sometimes it was pressed forward so the top of the head was uppermost. In other interments the body was extended its full length with face up. A large majority of the skulls had a bowl<sup>1</sup> inverted over them, though I judge twenty per cent were without any bowl. . . . In a great many instances after the body had been placed in the grave with bowl over the head, a little soil was filled in, and about one foot of adobe mud was added and tramped down then filled up with soil. This adobe mud is almost like rock, making it difficult to dig up the bowl without smashing it. . . . No article of any kind except the bowl over the head was found in any grave. In one case a bowl was found with a skull under it and under that skull was another bowl and another skull.

Few evidences of upright walls of buildings are found at or near this site. The surface of the ground in places rises into low mounds devoid of bushes, which grow sparingly in the immediate neighborhood, but no trees of any considerable size were noticed in the vicinity. Before work began at this place the only signs of former occupancy by aborigines, besides walls, were a few broken fragments of ancient pottery, metates, or a burnt stump protruding here and there from the ground. None of the house walls projected very high above the surface of the ground. Excavations in the floors of rooms at this point yielded so many human skeletons that the place was commonly referred to as a cemetery, but all indications support the conclusion that it was probably a village site with intramural interments.

The human burials here found had knees flexed or drawn to the breast in the "contracted" position, sometimes with the face turned eastward. The skeletons were sometimes found in shallow graves, but often were buried deeply below the surface. Almost without exception the crania had bowls fitted over them like caps. The graves as a rule are limited to soft ground, the bowls resting on undisturbed sand devoid of human remains. In some instances there appears to have been a hardened crust of clay above the remains, possibly all that is left of the floor of a dwelling. The indications are that here, as elsewhere, the dead were buried under the floors of dwellings, as is commonly the case throughout the Mimbres Valley. While there is not enough of the walls above ground to show the former extent

---

<sup>1</sup> On some of the skulls excavated at Sikyatki, Arizona, in 1895, the author found concave disks of kaolin perforated in the center. One of these disks is represented in Fig. 356, p. 729, 17th Ann. Rep. Bur. Amer. Ethnol. In an article on "Urn Burial in the United States" (*Amer. Anthropol.*, vol. 6, No. 5), Mr. Clarence B. Moore, quoting his own observations and those of many others, records burials in which an inverted mortar, bowl, basket, or other object was placed over the skull of the dead, and shows the wide distribution of the custom.

of the dwellings, the indications are that they were extensive and have been broken down and washed away.

#### OLDTOWN RUIN

Near where the Mimbres leaves the hills and, after spreading out, is lost in the sand, there was formerly a "station," on the mail route, called Mimbres, but now known as Oldtown. Since the founding of Deming, the railroad center, the stage route has been abandoned and Mimbres (Oldtown) has so declined in population that nothing remains of this settlement except a ranch-house, a school-house, and a number of deserted adobe dwellings.

Oldtown lies on the border of what must formerly have been a lake and later became a morass or cienega, but is now a level plain lined on one side with trees and covered with grass, affording excellent pasturage. From this point the water of the Mimbres River is lost, and its bed is but a dry channel or arroyo which meanders through the plain, filled with water only part of the year. In the dry months the river sinks below the surface of the plain near Oldtown reappearing at times where the subsoil comes to the surface, and at last forms Palomas Lake in northern Mexico.

In June, when the author visited Oldtown, the dry bed of the Mimbres throughout its course could be readily traced by a line of green vegetation along the whole length of the plain from the Oldtown site to the Florida Mountains.<sup>1</sup>

The locality of emergence of the Mimbres from the hills or where its waters sink below the surface is characteristic. The place is surrounded by low hills forming on the south a precipitous cliff, eighty feet high, which the prehistoric inhabitants chose as a site of one of their villages; from the character and abundance of pottery found, there is every reason to suppose this was an important village.

The Oldtown ruin is one of the most extensive seen by the author during his reconnoissance in the Deming Valley, although not so large as some of those in the Upper Mimbres, or on Whiskey Creek, near Central. Although it is quite difficult to determine the details of the general plan, the outlines of former rectangular rooms are indicated by stone walls that may be fairly well traced. There seem to have been several clusters of rooms arranged in rows, separated by square or rectangular plazas, unconnected, often with circular depressions between them.

---

<sup>1</sup>A beautiful view of the valley can be obtained from the top of Black Mountain, above the small ruin at its base, that will be mentioned presently.

There is considerable evidence of "pottery hunting" by amateurs in the mounds of Oldtown, and it is said that several highly decorated food bowls adorned with zoic figures have been taken from the rooms. It appears that the ancient inhabitants here, as elsewhere, practised house burial and that they deposited their dead in the contracted position, placing bowls over the crania (fig. 1).<sup>1</sup>

The author excavated several buried skeletons from a rectangular area situated about the middle of the Oldtown ruin, surrounded on three sides by walls. The majority of the dead were accompanied

FIG. 1.—Urn burial. (Schematic.)

with shell beads and a few turquoise ornaments, and on one was found a number of shell tinklers made of the spires of seashells. One of the skeletons excavated by Mr. Osborn appeared to have been enclosed in a stone cist with a flat slab of stone covering the skull. The remains of a corner post supporting the building stood upright on this slab.<sup>2</sup> In another case a skull was found broken into fragments by the large stone that had covered it. Several skeletons had no bowls

<sup>1</sup> The drawings of pottery designs in this article were made by Mrs. M. W. Gill; the stone and other objects were drawn by Mr. R. Weber.

<sup>2</sup> A significant feature in the Mimbres form of "urn burial" is the invariable puncturing of the bowl inverted over the head. The ancient Peruvians in some instances appear to have "killed" their mortuary bowls, and life figures depicted on Peruvian pottery are sometimes arranged in pairs as in the Mimbres.

over the heads, an exceptional feature in Mimbres burials; and in some instances the bowl had been placed over the face. In the case of numerous infant interments the bowl covered the whole skeleton.

#### RUIN ON BYRON RANCH

This ruin lies not far from the present course of the Mimbres near the Little Florida Mountains. The place has long been known as an aboriginal village site and considered one of the most important in the valley. The remains of buildings cover a considerable area. They have a rudely quadrangular form, showing here and there depressions and lines of stones, evidently indicating foundations of rooms, slightly protruding from the ground. Although this ruin has been extensively dug over by those in search of relics, no systematic excavations seem to have been attempted. It is said that valuable specimens have been obtained here, and fragments of pottery, arrowheads, and broken stone implements are still picked up on the surface.

The important discovery of burial customs of the ancient Mimbres was made by Mr. Duff at this ruin. He excavated below the floor of one of the rooms and found a human cranium on which was inverted a food bowl pierced in the middle, the first example of this custom noted in the Mimbres region.

#### RUIN NEAR DEMING

About seven miles northwest of Deming, in a field on the north side of the Southern Pacific Railroad, there is a small tract of land

FIG. 2.—Paint mortar. Diam.  $2\frac{1}{2}$ ".

showing aboriginal artifacts strewn over the surface, affording good evidence of prehistoric occupation. There are no house walls visible at this place, and only a few fragments of food bowls, but in the course of an hour's search several small mortars (fig. 2), paint grinders and other objects were procured at this place.<sup>1</sup>

<sup>1</sup> Although not placed in the proper locality on his map, this ruin seems to be one of the "pueblos" (Nos. 162-164) mentioned by Dr. Hough.

## PREHISTORIC SITE NEAR BLACK MOUNTAIN

Walls and outlines of rooms indicated by rows of stones mark remains of a prehistoric settlement at the base of Black Mountain, eight or nine miles northwest from Deming. Here occur many fragments of pottery, broken metates, and manos, and other indications of occupation by man. On top of Black Mountain there are rude cairns or rings of stones apparently placed there by human hands.

The fragments of pottery taken from the ruin at the base of Black Mountain are very different from those from Oldtown and other typical Mimbres ruins. Its color on the outside is red, with a white interior surface decorated with black geometric designs, the border is flaring often with exceptional exterior decoration. These bowls have broken encircling lines—a feature yet to be found in other Mimbres pottery—and none of the few pieces yet obtained from the ruin near Black Mountain has animal pictures. The whole appearance of this pottery recalls old Gila ware and suggests an intrusion from without the Mimbres region, possibly from the north and west.

The circles of stones on the top of Black Mountain have many points of resemblance to similar structures on hilltops near Swarts' Ranch on the Upper Mimbres, described by Mr. Webster, as follows:<sup>1</sup>

The tops of nearly all the mountains of this valley, and particularly those here mapped, are occupied by hundreds of rock mounds, breastworks, pits, etc. The region shown in plate 3, and which represents an area about one mile in length and three-fourths mile in width, exhibits 240 of these structures. . . . These rock mounds are composed of more or less rounded rocks gathered from the region, and generally weighing from four to eight pounds each; although many are smaller: and again others weigh from twenty-five to fifty pounds or more each. These structures are generally circular: although at times they are ovate, and again assume an oblong or linear marginal outline. They vary considerably in size, although usually being only from three to four feet in diameter: the linear ones being from six to eight feet or more in length. Some of the larger circular mounds assume a diameter of seven to eight feet. The height of these mounds varies considerably; but as a rule assume a height ranging from one to one and a half feet.

The distance apart of these structures is variable; being as a general thing from five to fifteen feet; but not infrequently they are only two to four feet apart: at other times, however, they may be observed to be from sixty to ninety feet or more distant from each other.

---

<sup>1</sup> *Archæological and Ethnological Researches in Southwestern New Mexico, Part 2, Ruin, Ancient Work Shop, Rock Mounds, etc., at Swarts' Ranch.* (*The Archæological Bulletin*, vol. 4, No. 1, p. 14, 1913.)

Mr. Webster discovered on a rocky ridge near Swarts' ruin, somewhat higher on the Mimbres than Brockman's Mill, seven similar earthen pits of much interest, which remind the author of subterranean or half-sunken dwellings. They are saucer-shaped or linear depressions, averaging about two feet in depth; when circular they are from five to fifteen feet in diameter the linear form in one instance being fifty feet long. Some of these have elevated margins, others with scarcely any marginal ridge. The western margin in one instance has a "wall of rounded stones."

There are similar saucer-shaped depressions near Brockman's Mills and elsewhere in the Mimbres, almost identical with "pit dwellings" found by Dr. Hough near Los Lentos. These saucer-like depressions, often supposed to have been the pits from which adobe was dug, were also places of burial, the dead being presumably interred under or on the floors; the original excavation being a dwelling that was afterwards used as a burial place for the dead. Their form suggests the circular kiva of the Pueblos and has been so interpreted by some persons.

#### RUINS ON THE MIMBRES RIVER FROM OLDTOWN TO BROCKMAN'S MILLS

On low terraces elevated somewhat above the banks of the river, between Oldtown and Brockman's Mills, there are several village sites, especially on the western side.<sup>1</sup> The most important of these is situated about four miles north of Oldtown. The ruin at the Allison Ranch, situated at the Point of Rocks where the cliffs come down to the river banks, is large and there are many pictographs nearby. The ruins at Brockman's Mills on the opposite or eastern side of the river lie near the ranch-house. Many rooms, some of which seem to have walls well plastered, can be seen just behind the corral. North of the ruin is a hill with low lines of walls like trincheras. On some of the stones composing these walls and on neighboring scattered boulders, there are well-made pictographs.<sup>2</sup>

#### PICTOGRAPHS

Pictographs occur at several localities along the Mimbres. As these have a general likeness to each other and differ from those of other regions, they are supposed to be characteristic of the prehistoric

<sup>1</sup> For a description of ruins at Swarts' and Brockman's Mills see C. L. Webster, *Archaeological and Ethnological Researches in Southwestern New Mexico*. (The *Archaeological Bulletin*, vol. 3, No. 4.)

<sup>2</sup> It is said that a Spanish bell in the Chamber of Commerce at Deming, was dug up on this ranch near the ruin. This bell might indicate an old mission at this place.

FIG. 3.—Pictographs.

people. They are generally pecked on the sides of boulders or on the face of the cliffs in the neighborhood of prehistoric sites of dwellings. Although there is only a remote likeness between these pictographs and figures on pottery, several animal forms are common to the two.

The most important group of pictographs (fig. 3) seen by the author are situated about nine miles from Deming in the western foot-hills of Cook's Peak.<sup>1</sup> Some of the pictographs recall decorations on bowls from Pajarito Park.

Another large collection of Mimbres pictographs, visited by the author, is found at Rock Canyon, three or four miles above Oldtown, at a point where the cliffs approach the western bank of the river. On the river terrace not far above this collection of pictures, also on the right bank of the river, lies the extensive ruin of a prehistoric settlement, the walls of which project slightly above the surface. This ruin has been dug into at several points revealing several fine pieces of pottery, fragments of metates, and other implements, which are said to have been found in the rooms. A mile down the valley overlooking the river there is another cluster of pictures at a ruin called "Indian graveyard," probably because human skeletons have been dug out of the floors of rooms.

#### MORTARS IN ROCK IN PLACE

One of the characteristic features of the Mimbres ruins, but not peculiar to them, are mortars or circular depressions worn in the horizontal surface of rock in place. They are commonly supposed to have been used as mortars for pounding corn, and vary in size from two inches to a foot in diameter, being generally a foot deep. We find them occurring alone or in clusters. Good examples of such depressions are found near the Byron ruin, in the neighborhood of the ruins along Whiskey Creek, at Oldtown, and elsewhere. There is a fine cluster of these mortars nine miles from Deming, near the pictographs in the Cook's Range. Similar mortars have been repeatedly described and often figured. Mr. Webster has given the most complete account of this type of mortars in a description of the ancient ruins near Cook's Peak.<sup>2</sup> On the surface of the southwestern

---

<sup>1</sup> The author visited these rocks in company with Dr. Swope, who has known of them for many years.

<sup>2</sup> *Archæological and Ethnological Researches in Southwestern New Mexico*, Part 4. (*The Archæological Bulletin*, vol. 5, No. 2, p. 21.)

point of a low hill to the north of an ancient ruin at Cook's Peak, according to this observer,

occurs a feature which the writer had nowhere else seen, save on the east side of the same mountain. I refer to the great number of mortars which occur in this sandstone back a few feet to the north of the ruins, and which were made and long used by the ancient pueblo-dwellers. There exists at this one place fifty-three of these mortars, nearly all of them occurring in an area of surface not more than seventy-five or eighty feet in diameter. . . . Nearly all the mortars are circular or sub-circular in outline, symmetrical and smooth inside, and the upper edge or margin usually rounded by the pestle. In a few cases, however, these mortars have an oblong or subovate outline, somewhat like some forms of metates found among the ruins.

These mortars often contract to a point at the bottom, when circular in marginal outline, although at times are longer than broad, as just stated, and in this case have a more flattened bottom. They vary from two to eleven inches in diameter, the smallest forms being those apparently only just begun, and are few in number. The deepest mortar observed was seventeen inches, though the great majority of them would vary perhaps from four to ten inches in depth. Often the rock was smooth and polished around the margin of the mortars, and [their distances apart] vary from a few inches to several feet from each other.

At times these mortars would be located on the top of a large block of sandstone which might happen to occupy this area; these boulders sometimes being four to five feet in diameter and perhaps four feet in height. It was plain to be seen that this ancient mill-site was long used by these peculiar people, but just why so many quite similar mortars should have been made here and used by these people is a matter of conjecture.

It seems certain that a sufficiently large number of people could not have been congregated here, under ordinary conditions, to warrant the forming of so many mortars for the purpose of grinding food.<sup>1</sup>

The present writer accepts the theory that these rock depressions were used in pounding corn or other seeds, but their great number in localities where ruins are insignificant or wanting is suggestive. We constantly find arable land near them, indicating that communal grinding may have been practised, and suggesting a large population living in their immediate neighborhood, which may have left no other sign of their presence.

#### MINOR ANTIQUITIES

The artifacts picked up on the surface near ruins or excavated from village sites resemble so closely those from other regions of the Southwest that taken alone these do not necessarily indicate special

---

<sup>1</sup> Mr. Webster describes "ancient pueblos" on the western side of this group of mountains as well as on the eastern slope of Cook's Range. Certain cave lodges, or walled caves, in a wild canyon on the east side of Cook's Peak are supposed by him to be the recent work of Apaches.

culture areas. A few of the more common forms from the Mimbres are here figured for comparison, but, with the exception of the pottery, there is little individuality shown in the majority of these objects. Among other objects may be mentioned stone implements, mortars, idols, bone implements, shell ornaments, and pottery.

#### STONE IMPLEMENTS

The stone axes are not very different from those of the Rio Grande and the Gila, but it is to be noticed that they are not so numerous as in

FIG. 4.—Stone axe.  
Length 8 $\frac{3}{4}$ ".

FIG. 5.—Arrow polisher. Length 3 $\frac{1}{4}$ ",  
breadth 2 $\frac{1}{2}$ ".

the latter region, and are probably inferior in workmanship, fine specimens indeed being rare. The majority of the axes (fig. 4) are single grooved, but a few have two grooves. In Dr. Swope's collection, now in the Deming High School, there is a fairly good double-bladed axe.

Miss Ahutt, of Deming, has a remarkable collection of arrow-points gathered from many localities in the valley, and also a few fine spearpoints, conical pipes, and other objects taken from the sacred spring at Faywood Hot Spring. A beautiful arrow polisher found near Deming is shown in figure 5.

The pipes from the Mimbres take the form of tubular cloud-blowers, specimens of which are shown in figure 6. Apparently these pipes were sometimes thrown into sacred springs, but others have been picked up on the surface of village sites or a few feet below the surface.

FIG. 6.—Cloud blowers. Faywood Hot Springs. (Swope collection.)  
 $\frac{1}{2}$  nat. size.

Lateral and top views of one of the characteristic forms of small stone mortars with a handled projection on one side is shown in figure 7. This specimen is in the Swope collection in the Deming

FIG. 7.—Handled mortar. (Swope collection.) Length  $10\frac{3}{4}$ ".

High School. In the same collection there are also two beautiful tubular pipes, or cloud-blowers, from the same spring.

The stone mortars from Mimbres ruins vary in size. Many are simply spherical stones with a depression on one side; others are larger but still spherical, or ovate; while others have square or

rectangular forms. The most remarkable feature in these is the presence of a handle on one side, which occasionally is duplicated, and in one instance four knobs or legs project from the periphery. These projections appear to characterize the mortars of the Mimbres, although they are not confined to them, as the form occurs in other regions of New Mexico and in California. One of the most instructive of these small spherical paint mortars, now owned by Mr. E. D. Osborn, has ridges cut in high relief on the outside.

Metates and manos, some broken, others whole, are numerous and can be picked up on almost every prehistoric site. While some of these metates are deeply worn, showing long usage, others have margins but slightly raised above the surface. The majority of metates found on the sites of habitations have no legs, but a typical Mexican metate with three knobs in the form of legs was presented to the National Museum by the Rev. E. S. Morgan, of Deming. Metates are sometimes found in graves with skeletons, presumably those of women. Several ancient metates are now in use as household implements in Mexican dwellings.

If the size of the population were to be gauged by the number of mortars and manos found, certainly the abundance of these implements would show that many people once inhabited the plain through which flows the Mimbres River. Narrow, flat stone slabs have an incised margin on one end. Their use is problematical. The frequency of stone balls suggests games, but these may have been used as weapons; or again, they were possibly used in foot races, as by the Hopi of to-day.

#### COPPER OBJECTS

Native metallic copper was formerly abundant at the Santa Rita mines, and there is every probability that the material out of which some of the aboriginal copper bells were made was found here, and that these mines were the source of float copper found in Arizona ruins. Although no copper implements were found by the author in the Mimbres ruins, he has been told that objects of copper apparently made by the aborigines have been found in some of the graves.<sup>1</sup>

---

<sup>1</sup> Elaborate metal objects of early historical times have been found at various places in the Mimbres. The best of these is a fragment of an elaborately decorated stirrup, now owned by Mr. Pryor of the Nan Ranch. A copper church bell was found near his house, and other metal objects belonging to the historic epoch are reported from various ruins in the valley.

## STONE IDOLS

The author saw several stone idols that were reported to have been obtained from ruins in the Mimbres Valley. These idols represent frogs (fig. 8), bears, mountain lions, and other quadrupeds, and have much the same form as those from ancient ruins in Arizona.<sup>1</sup>

FIG. 8.—Frog fetish. Black Mountain Ruin. (Swope collection.) Length  $3\frac{1}{2}$ ".

On the backs of several of these stone idols are incised figures, like arrowheads tied to Zuñi fetishes, or possibly rain-cloud figures. In one instance they were made on an elevated ridge, which unfortunately was broken. The author has also seen several small amulets,

FIG. 9.—Fetish. Byron Ranch. (Swope collection.) Length  $5\frac{3}{4}$ ".

FIG. 10.—Fetish. Byron Ranch. (Swope collection.) Length  $6\frac{3}{4}$ ".

perforated apparently for suspension. The stone idols here figured (figs. 8, 9, 10) were presented to the Deming High School by Dr. Swope.

<sup>1</sup> Similar stone idols from the San Pedro Valley and other localities, in Arizona and New Mexico, have mortar-like depressions on their backs.

## SHELL BRACELETS AND CARVED SHELLS

Two or three shell bracelets were excavated from Mimbres ruins, and there were also found carved shells and tinklers not unlike those of northern New Mexico ruins. Some of these when excavated were found near the head and are supposed to have been earrings. Five shell rings were still on the bones of the forearm of a child when found. One of the shell bracelets owned by Mr. Osborn was cracked but was pierced on each side of the break, indicating where it had been mended; another had figures incised on its surface, and a third had the edges notched, imparting to it a zigzag shape, like that of a serpent. Many shell beads, spires of shells used for tinklers, and other shell objects, all made of genera peculiar to the Pacific Ocean, were found during the excavations.

## POTTERY

## FORMS AND COLORS

The comparatively large number of vases, food bowls, and other forms of decorated smooth ware in collections from the Mimbres is

FIG. 11.—Braided handle.  
 $\frac{1}{2}$  nat. size.

FIG. 12.—Small bowl.  
Diam.  $3\frac{1}{2}$ ".

largely due to their use in mortuary customs, and the fact that almost without exception they were found placed over the skulls of the dead. Although the largest number of vessels are food bowls, there are also cups with twisted handles (fig. 11), bowls (fig. 12), vases, dippers, and other ceramic forms found in pueblo ruins.<sup>1</sup>

Coarse, undecorated vessels showing coils, indentations, superficial protuberances, and other rude decorations like those so well known in Southwestern ruins, are well represented. Some of these were

<sup>1</sup> One of the exceptional forms of pottery has a flat rectangular base, the four sides being formed by bending up segments of a circular disk (fig. 18).

used as cooking vessels, as shown by the soot still adhering to their outer surface. While the majority of bowls were broken in fragments when found, a few were simply pierced through the bottom; one or two were unbroken or simply notched at the edge.

The colors of Mimbres ware are uniform and often striking. There are good specimens of black and white ware; also red, black, and yellow with brown decorations are numerous. Some of the best pieces are colored a light orange. Many of the fragments are made of the finest paste identical in color and finish with ware from Casas Grandes, Chihuahua, which furnishes the best prehistoric pottery from the Southwest. No effigy jar, or animal formed vase, however, exists in any collections from the Mimbres examined by the author.

Ruins in the Lower Mimbres have thus far yielded a larger variety and a finer type of pottery than ruins on the banks of the river among the hills, which is in part due to the extent of excavations. The Old-town potters developed a kind of pottery with characteristic ornamentation found both in ruins in the plain to the south and along the narrow valley of the Mimbres to the north.

The Mimbres pottery, like all other ancient ware from the Southwest, frequently shows evidences of having been mended. Holes were drilled near the breaks and fibers formerly united the parts thus holding the bowl together even though broken. As one goes south, following the course of the river, the character of the pottery changes very slightly, but if anything is a little better.

The food bowls generally have a rounded base, but one specimen is flat on the bottom. The edges of the bowls from the ruin at Black Mountain are curved outward, an exceptional feature in ancient Pueblo vessels but common in modern forms.

#### PICTURES ON MIMBRES POTTERY

The great value of the ceramic collection obtained from the Mimbres is the large number of figures representing men, animals, and characteristic geometrical designs, often highly conventionalized, depicted on their interiors. These figures sometimes cover a greater part of the inner surface, are often duplicated, and are commonly surrounded by geometrical designs or simple lines parallel with the outer rim of the vessel. It is important to notice the graceful way in which geometrical figures with which the ancient potters decorated their bowls are made to grade into the bodies of animals, as when animal figures become highly conventionalized into geometrical designs. Although these decorations are, as a rule, inferior to

those of the Hopi ruin, Sikyatki, the figures of animals are more numerous, varied, and realistic.

The ancients represented on their food bowls men engaged in various occupations, such as hunting or ceremonial dances, and in that way have bequeathed to us a knowledge of their dress, their way of arranging their hair, weapons, and other objects adopted on such occasions. They have figured many animals accompanied by conventional figures which have an intimate relation to their cults and their social organization. Although limited in amount and imperfect in its teaching this material is most instructive.

FIG. 13.—Hunters. Oldtown Ruin. (Osborn collection.)

#### GROUP OF HUNTERS

An instructive group of human figures is drawn on a deep red and white food bowl (fig. 13), which measures ten inches in diameter. It is evident that this design represents three hunters following the trail of a horned animal, probably a deer. This trail is represented on the surface of the bowl by a row of triangles, while the footprints of the hunters extend along its side. It may be noted that although there are three hunters, the trails of two only are represented, and that the hunters are barefoot. They have perhaps lost the trail and

are looking the opposite way, while the animal has turned back on his path. The footprints of the deer in advance of the hunters are tortuous, showing want of decision on the part of the animal. The three hunters are dressed alike, wearing the close-fitting jacket probably made of strips of skin woven together like that found by Dr. Hough in a sacrificial cave at the head of the Tulerosa, New Mexico. Each carries a bow and arrow in his right hand, and in his left a stick which the leader uses as a cane; the second hunter holds it by one end before him, and the third raises it aloft. These objects are supposed to represent either weapons or certain problematic wooden staffs with feathers attached, like divining rods, by which the hunters are in a magical way directed in their search. The first hunter "feels" for the lost trail by means of this rod.

An examination of the pictures of the arrows these hunters carry shows that each has a triangular appendage at the end representing feathers, and small objects, also feathers, tied to its very extremity. The hair of the third hunter appears to be a single coil hanging down the back, but in the other two it is tied in a cue at the back of the head. The eyes are drawn like the eyes on Egyptian paintings, that is, the eye as it appears in a front view is shown on the side of the head. The right shoulders of all are thrown out of position, in this feature recalling primitive perspective. The information conveyed by this prehistoric picture conforms with what is known from historical sources that the Mimbres Valley formerly abounded in antelopes, and we have here a representation of an aboriginal hunt.

#### FIGURE OF A WOMAN

A black and white bowl (pl. I, fig. 1) is twelve and one-half inches in diameter and six inches deep. Upon this bowl is drawn a figure of a human being, probably a woman or a girl, seen from the front. Although portions of the figure are not very legible, such details as can be made out show a person wearing a blanket that extends almost to the knees leaving arms and legs bare, the lower limbs being covered. The head is square, as if masked, with hair tied at each lower corner. Although these appendages may be meant to represent ear-pendants, it is more likely that they are whorls of hair, as is still customary in Pueblo ceremonies in personations of certain maidens. Across the forehead are alternating black and white square figures arranged in two series, recalling corn or rain-cloud symbols. The neck is adorned by several strands of necklaces, the outermost of which, almost effaced, suggests rectangular ornaments. The garment worn by the

figure is evidently the ceremonial<sup>1</sup> blanket of a Pueblo woman, for no man wears this kind of garment. It has a white border and from its middle there hangs a number of parallel lines representing cords or a fringe, evidently the ends of a sash by which the blanket was formerly tied about the waist. It is instructive to notice that we find similar parallel lines represented in a picture of a girl from Sikyatki<sup>2</sup> where the blanket has the same rectangular form as in the prehistoric Mimbres picture. There can be no question that in this case it represents a garment bound with a girdle, or that the picture was intended for that of a girl or a woman. We have in this picture evidence that the same method of arranging the hair was used in the Mimbres Valley as in northern New Mexico. The leg wrappings suggest those used by Pueblo women, especially the Hopi, whose leggings are made of long strips of buckskin attached to the moccasins and wound around the lower limbs.

#### PRIEST SMOKING

The third human figure, found on a black and white bowl from a Mimbres ruin, is duplicated by another of the same general character depicted on the opposite side of the bowl. These figures (fig. 14) are evidently naked men with bands of white across the faces. The eyes are represented in the Egyptian fashion. In one hand each figure holds a tube, evidently a cloud-blower or a pipe, with feathers attached to one extremity, and in the other hand each carries a triangular object resembling a Hopi rattle or tinkler. The posture of these figures suggest sitting or squatting, but the objects in the extended left hand would indicate dancing. The figure is identified as a man performing a ceremonial smoke which accompanies ceremonial rites.

#### MAN WITH CURVED STICK

One of the most instructive food bowls found at Oldtown, now owned by Mr. Osborn, has on it a picture of two hunters, one on each side of an animal (fig. 15). One of these hunters carries in his hand a stick crooked at the end, its form suggesting a throwing stick.<sup>3</sup> Both hunters have laid aside their quivers, bows, and arrows, which are shown behind them. The picture of an animal between them has been so mutilated by "killing" or breaking the bowl that it is impos-

<sup>1</sup> Called also a "wedding blanket" since it is presented to a girl on marriage by her husband's family.

<sup>2</sup> 17th Ann. Rep. Bur. Amer. Ethnol., pl. 129, fig. *a*.

<sup>3</sup> The hand of the hunter pictured on a bowl already described (fig. 13), also carried a curved stick.

FIG. 14.—Priest smoking. Osborn Ruin.

FIG. 15.—Man with curved stick. Oldtown Ruin. (Osborn collection.)  
Diam.  $5\frac{1}{2}$ ".

sible to identify it. From the end of this crook to the body of the animal there extend two parallel lines of dots indicating the pathway of a discharged weapon. Near the body of the animal these rows of dots take a new direction, as if the weapon had bounded away or changed its course. The rows of dots are supposed to represent lines of meal by which Pueblos are accustomed to symbolically indicate trails or "roads."

There is, of course, some doubt as to the correct identification of the crooked staff as a throwing stick, for as yet no throwing stick has been found in the Mimbres ruins. The resemblance of the crooked stick to those on certain Hopi altars and its resemblance to emblems of weapons carried by warrior societies is noteworthy. Crooked sticks of this character have been found in caves in the region north of the Mimbres.<sup>1</sup>

We find a survival of a similar crook used as sacred paraphernalia in several of the Hopi ceremonies, where they play an important rôle. As the author has pointed out, crooked sticks or *gnelas* (fig. 16) identified as ancient weapons surround the sand picture of the Antelope altar in the Snake Dance at Walpi, and in Snake altars of other Hopi pueblos, but it is in the Winter Solstice Ceremony, or the *Soyaluña*, at the East Mesa of the Hopi, that we find special prominence given to this warrior emblem. During this elaborate festival every Walpi and Sitcomovi kiva regards one of these *gnelas* as especially efficacious for the warriors, and it is installed in a prominent place on the kiva floor, as indicated in the author's account of that ceremony.<sup>2</sup>

The following explanation of these crooks was given him by the priests:

These crooks or *gnelas* have been called warrior prayer sticks, and are symbols of ancient weapons. In many folk tales it is stated that warriors overcame their foes by the use of *gnelas* which would indicate that they had something to do with ancient war implements. Their association with arrows on the Antelope altars adds weight to this conclusion.

The picture from Oldtown ruin of the hunter who has laid aside the quiver, bow, and arrow, and is using a similar *gnela*,<sup>3</sup> corroborates this interpretation.

Not all crooked sticks used by the Hopi are prayer sticks, or weapons, for sometimes in Hopi ceremonials a number of small shells are

---

<sup>1</sup> Bull. 87, U. S. National Museum.

<sup>2</sup> The Winter Solstice Ceremony at Walpi. Amer. Anthropol., 1st ser., vol. 11, Nos. 3, 4, pp. 65-87, 101-115.

<sup>3</sup> An ancient crook found in a cave near Silver City is figured by Dr. Hough. Bull. 87, U. S. National Museum.

tied to the extremity of a crooked stick forming a kind of rattle. In the Flute Ceremony a crooked stick is said to be used to draw down the clouds when the rain they contain is much desired.

Figure 16 is a representation of one of the crooks which was specially made for use in the Soyaluña at Walpi, in 1900. Similar crooks were set upright in a low mound of sand on the floors of all the kivas. Extending from the base of the crook to the ladder there

FIG. 16.—Hopi curved stick. Length 8".

was sprinkled a line of meal called the road (of blessings), over which was stretched a feathered string attached to the end of the crook. Midway in the length of the crook was attached a packet of prayer meal wrapped in cornhusk and a feather of the hawk, a bird dear to warriors, and other objects, which indicated a prayer offering. At the termination of ceremonies in which these crooks are made and blessed as prayer emblems by the Hopi they are deposited in shrines as recorded.

The crook (gnela) is used as a prayer emblem of warriors because it has the form of an ancient weapon, and while it assumes modifications in different Hopi ceremonies it apparently has one and the same intent, as in Soyaluña. This crook is sometimes interpreted as symbolically representing an old man with head bent over by age, but this interpretation is probably secondary to that suggested above, as so often happens in the interpretations given by primitive priests.

The true interpretation of the crooked prayer stick was pointed out by the author in his article on "Minor Hopi Festivals,"<sup>1</sup> as follows:

This crook is believed by the author to be a diminutive representation of an implement akin to a throwing stick, the object of which is to increase the

FIG. 17.—Human figure running. Oldtown Ruin. (Osborn collection.)  
Diam.  $7\frac{1}{2}$ ".

velocity of a shaft thrown in the air. Its prototype is repeatedly used in Hopi rites, and it occurs among Hopi paraphernalia always apparently with the same or nearly the same meaning.

In figure 17 is represented a person running with outstretched banded arms, holding in the left hand a bow, and in the other a straight stick. The head is circular with cross lines, a round, dotted eye, and two triangular ears. Another representation shows a human figure with a bow and arrow before the hands, accompanied by three animals, the middle one being a bird and the two lateral, quadrupeds.

<sup>1</sup> Amer. Anthropol., n. s., vol. 4, p. 502.

By far the most unusual group of human forms consists of two figures, one male, the other female, depicted on another bowl. The action in which these two are engaged is evident. The female figure has dependent breasts and wears a girdle. One hand is raised and brought to the face and the other carries a triangular object. The female figure has three parallel marks on the cheek, like the Hopi war-god. Behind the woman are several curved lines depicting unidentified objects.

The figure shown on one bowl (fig. 18) has several marked features, but the author is unable to suggest any theory of identification. It seems to be a seated figure with a human head, arms, and legs, the toes and fingers being like hands and feet. The forearm is drawn on the shoulder in the same way as in the one of the hunters (fig. 13).

FIG. 18.—Unidentified animal and bowl of unusual form. Oldtown Ruin. (Osborn collection.)

The eye, nose, and mouth are also human, but the body is more like that of an animal. The appendages back of the head are similar to those interpreted as feathers on the heads of certain animal designs.

On the theory that this is a seated human figure it is interesting to speculate on the meaning of the curved object represented on the surface of the bowl, extending from one hand to the foot. This object has the general form of a rabbit stick or boomerang, still used by the Hopi in rabbit hunting.<sup>1</sup>

<sup>1</sup> Rabbits are abundant in the Mimbres Valley and several well-drawn pictures of this animal are found on the pottery.

The well-drawn figure painted on a bowl (pl. 1, fig. 2) from Oldtown ruin represents a man with knees extended and arms raised as if dancing. This picture has characteristic markings on the face, but otherwise is not distinctive.

#### QUADRUPEDS

*Wolf*.—Although there are not sufficiently characteristic features represented in the next figure (pl. 2, fig. 1)<sup>1</sup> to identify it satisfactorily, the form of the head, tail, mouth, and ears suggests a wolf.<sup>2</sup> The square design<sup>3</sup> covering one side of the body seems to the

FIG. 19.—Antelope. (Osborn collection.) Diam. 10".

author not to belong to the animal itself, for an Indian who could represent an animal as faithfully as those here pictured would not place on it such markings unless for a purpose. It resembles the small blankets sometimes worn by pet dogs or horses among white people, which is a lame explanation, as dog and horse blankets were

<sup>1</sup> This picture resembles that of a wolf depicted on the east wall of the warrior chamber at Walpi. See *Amer. Anthropol.* n. s., vol. 4, pl. 22.

<sup>2</sup> Pictures of the mountain lion by Pueblo artists, at least among the Hopi, have the tail turned over the back. The animal on the Mimbres bowl having no horns is not a horned deer or antelope.

<sup>3</sup> The decoration of the bodies of animals with rectangular figures is a common feature in Mimbres pottery, as will be seen in pictures of birds soon to be considered.

unknown among Indians. The only theory the author has formed regarding this geometrical figure is that it is a variant of the Sikyatki habit of accompanying a figure of an animal with a representation of his shrine. This bowl is of black and white ware and is eleven inches in diameter by five and one-half inches deep.

*Antelope.*—There are two<sup>1</sup> figures of an animal with branching horns,<sup>2</sup> supposed to be an antelope, an animal formerly common in Mimbres Valley. In one of these (fig. 19) the head is held downward as if the animal were feeding; in the other (fig. 20) the neck is

FIG. 20.—Antelope. Osborn Ruin. Diam. 10".

extended. A pair of markings on the neck are identical with those on pictures of the antelope still painted on modern pottery made by the Zuñi. A band, resembling a checkerboard, is drawn across the body of one; on the other are parallel lines.

Another figure referred to as an antelope appears to represent a young fawn, since, while it has all the characteristics of this animal,

<sup>1</sup> In addition to the figure with the hunters which is probably a deer, as it has not the antelope marks on the neck.

<sup>2</sup> These horns are represented on a plane at right angles to that in which they naturally lie.

the horns are wanting. This specimen (fig. 21) was found at Oldtown. The rectangular shape so often given to the bodies of animals drawn on Mimbres pottery is well shown in this specimen.

FIG. 21.—Fawn. Oldtown Ruin.

FIG. 22.—Rabbit. Oldtown Ruin. Diam.  $7\frac{1}{2}$ ".

*Mountain Sheep.*—It is evident from the form of the unbranched horns, the slender legs, and the head, that either a mountain sheep or mountain goat was intended to be represented in plate 2, figure 2.

The markings on the body are symbolic, suggesting lightning, and it may be added that the Hopi depict the lightning on the artificial horns mounted on caps and worn by them in presentations of dances in which they personate mountain sheep.

*Rabbit or Hare.*—The pictured representation (fig. 31) of a quadruped whose hindlegs are larger than the forelegs and whose long backward extending ears are prominent features, probably represents a rabbit or a hare. The eyes recall figures of birds depicted on bowls from the Little Colorado ruins in Arizona, where eyes are

FIG. 23.—Mountain lion or wild cat.  
(Osborn collection.)

FIG. 25.—Bird E. Osborn Ruin.  
(Osborn collection.)

depicted on one side of the head in violation of a law of perspective in which only one eye can appear on a lateral view. The figure appears to have a tuft of grass in the mouth. The geometric markings on the body are different from those of any known species of rabbit and belong to the category of symbolic designs.

The author excavated at Oldtown a food bowl, the figure on which was undoubtedly intended for a rabbit (fig. 22). The head, ears, body, legs, and tail are well made, leaving no question of the intention of the artist; but if there were any doubt of the identification it is dispelled by the representation of the mouth, on which the sensitive hairs or bristles are represented.

*Mountain Lion.*—One of the Oldtown bowls is decorated with a representation of the wild cat or mountain lion, and is a fair example of archaic design (fig. 23). The feature that distinguished this quadruped is the position of the tail which, like those of Pueblo pictures of mountain lions or cats, is bent forward over the back.

Both head and body are rectangular and the legs are short and stumpy with sharp curved claws. The ears, mouth, and teeth have characteristic features of carnivora and the tail is banded, especially near the end.

The geometric design on the side of the body consists of an angular, S-shaped design with two equal armed stars, the latter associated with the mountain lion in Pueblo symbolism. The single figure drawn on this bowl occupied the middle of the interior, but in the next bowl this figure is duplicated.

The two figures on another bowl also represent some cat, or mountain lion, but the geometric figure on its body differs so much from the first specimen that it may belong to a different genus. The geometrical designs occur on both the anterior and posterior extremities of the rectangular body and consist of triangular figures with parallel lines and terraces recalling rain-clouds. This bowl is owned by Mr. E. D. Osborn, and was found at Oldtown. The decorations on the two quadrants alternating with the animal figures are bands from which other markings radiate to the side of the bowl.

*Badger.*—The quadruped drawn on the inside of a bowl found at Oldtown, and now owned by Mr. E. D. Osborn, has some resemblances to a badger, especially in the head, ears, teeth, and tail. The geometrical design on the body of this animal consists of an unequal sided rectangle enclosing four triangles with angles so approximated as to form an enclosed rectangle. The head has two bands extending longitudinally, apparently conventionalized markings characteristic of this animal, as they do not occur on deer, wildcats, or mountain sheep.

*Birds.*—As has been pointed out in the author's identifications<sup>1</sup> of designs on Sikyatki pottery, those representing birds are among the most abundant. The same holds also in the pottery from the Mimbres, where several figures identified as birds occur on food bowls. Two of these are duplicated on the same vessel, practically the same figure being repeated on opposite sides. In the latter case each member of the pair faces in an opposite direction or is represented as if moving with the middle of the bowl on the left.<sup>2</sup>

<sup>1</sup> 17th Ann. Rep. Bur. Amer. Ethnol., p. 682.

<sup>2</sup> This is known as the sinistral circuit and is regarded as beneficial in Hopi ceremonials.

The various birds differ considerably in their forms, organs, attitudes, and appendages. Two of the pictures seem to represent the same bird, but the others belong to different genera. There are one or two figures in which feathers can be distinguished, but as a rule they are fewer in number and the feathers less conventionalized than in Sikyatki pottery.

Pending the difficulty in identifying the various designs representing birds, they are designated by letters A, B, C, D, etc.

*Bird A.*—The figure shown in plate 3, figure 1, is represented by two designs, practically the same, repeated so far as appendages go, but quite different in the ornamentation of their bodies. One of these has the same geometrical figure on its body as on one of the quadruped pictures, the second has a different design. Both birds have wings outspread as if in flight, in which the feathers are well drawn in detail, especially the wing on the side turned toward the observer. That on the opposite side is simply uniformly black. The feathers of its companion on the other side of the bowl are indicated by parallel lines. The tail is long and forked at the extremity, suggesting a hawk, and is decorated for two-thirds of its length with cross-hatched and parallel lines. A triangular appendage arises from the under side of the tail at the point where the line decoration ends, forming an appendage which is likewise represented in the companion picture.

*Bird B.*—Bird B (pl. 3, fig. 2) is painted on the interior of a food bowl of black and white ware, ten inches in diameter by five inches deep. Its body is oval, the head erect and undecorated, and the tail twisted from a horizontal into a vertical plane as is customary in representation of lateral views of birds from Pueblo ruins. The geometric figure on the body is unfortunately somewhat obscured by the plaster used in mending, but several parallel bars that may represent feathers of the wings show through it, and a number of other designs or parallel lines are apparent. An appendage of triangular form hangs from the lower margin of the body and indicates the position of one leg; the other leg is missing.

*Bird C.*—Bird C, shown in plate 4, figure 1, occurs on a black and white bowl that measures ten inches in diameter, five and one-half inches in depth. The figure occupies the circular zone in the middle of the bowl and is enclosed by parallel lines which surround the bowl near the rim. The top of the head, which is globular, is white in color, the beak projecting and the eyes comparatively large. The body is likewise globular and is covered by a square geometrical design the details of which are considerably obscured by the hole in the middle of

the jar. A number of parallel lines of unequal length, turned downward, hang from the rear of the body and form the tail. The long legs suggest a wading bird, and the widely extended claws point to the same identification.

*Bird D.*—One of the most instructive figures of birds occurs on a bowl from Oldtown ruin. This bowl (fig. 24) is now owned by Mr. E. D. Osborn, by whom it was found. The bird depicted on it is seen from the back; its wings are drooping, and parallel lines indicate feathers. The legs, drawn backward, terminate in three toes, and the tail, slightly bent to one side, is composed of several feathers.

FIG. 24.—Bird D.  
(Osborn collection.)

FIG. 29.—Unidentified animal. Oldtown Ruin.  
(Osborn collection.)

The head is globular with two eyes on the back and a short pointed beak. As in all other zoic figures the geometric figures on the back of the body are the most characteristic. The middle of the body is occupied by an oval design through which may be seen the perforation with which the bowl was killed. At one end there is a triangular design with cross lines which extend partly over the oval figure where, except at one point, they are obscure.

Four quadrilateral designs are distributed at intervals around the oval figure. Each of these has sides of about equal length and a dot medially placed in a smaller figure contained in a larger.

*Bird E.*—The bird shown in figure 25 (p. 35) from the Osborn ruin has a body form not unlike that of plate 4, figure 1, but the geometric

design on the body, although rectangular, has incurved sides and is covered with cross lines suggesting a net. Its neck is girt by four rings, head small, without feathers, eye minute, bill comparatively long and pointed recalling that of a snipe which is also suggested by long legs and in a measure by the form of the tail.

This bird is undoubtedly aquatic, as indicated by the figure of a fish which it appears to be on the point of capturing or devouring.

*Bird F.*—The bird shown in plate 4, figure 2, is different from any of the above and is distinguished readily by the four curved lines on the head suggesting the quail. The pointed tail is marked above and below with dentations, formed by a series of rectangular figures which

FIG. 26.—Bird G. Oldtown Ruin. (Osborn collection.) Diam. 10".

diminish in size from body attachment to tip. The body itself is marked posteriorly with parallel lines, rectangular and curved figures suggesting wings.

The bowl (fig. 26) has three animals figured upon it forming a graceful combination. The most striking represents a long-billed bird with one wing notched on the inner margin. The tail of this bird is differently drawn from any of the other birds in the collection and has representations of six feathers. In front of this bird, with the point of the snout at the tip of the bill of the bird, is a lizard-shaped head covered with scales and two round eyes. The other remarkable figure also has extended forelegs, but the body is so broken that identification is quite impossible. Like the figure of the lizard, it also has a lozenge head and two eyes. The geometrical designs on the body are characteristic.

## ANIMALS NOT IDENTIFIED

*Unidentified Animal.*—It is difficult to tell exactly what animal was intended to be represented by that shown in plate 5, figure 2. Its head and mouth are not those of any of the horned animals already considered, although it has some anatomical features recalling a mountain sheep. The extension back of the body has a remote likeness to a fish, but may be a bird or simply a conventional design. The geometrical figure covering the side of the body bears some likeness to one depicted on a bird, as shown in plate 3, figure 1. The same geometrical figure sometimes also occurs separated from any animal form in Sikyatki pottery.<sup>1</sup>

The bowl is ten inches in diameter, five inches in depth, and the figures are painted red on a white ground.

*Unidentified Animal.*—One of the most remarkable of many figures on bowls from Oldtown in the collection of Mr. E. D. Osborn is shown in figures 27, 29 (p. 38). Three colors enter into the decoration of this bowl, black, white, and brown, and there are two types of ornamentation, one zoic, the other geometric. The bowl itself was much broken when found, but not so mutilated as to hide the main designs.

The zoic figures represent animals with square bodies, four legs, ears, head, and tail like a young antelope. There is no design on the side of the body, but in its place four broad parallel bands extend from the belly across the bowl. Each group of parallel lines changes its direction, widening in their course or near the ends where they enlarge for the accompanying figure. The markings on the necks of these figures suggest those on fawns.

The elaborate geometric figure composed of a scroll and comma-like dot and eye is a highly conventionalized symbol, possibly of some animal, as a bird's head, common on Casas Grandes pottery.

There is a bowl on exhibition in the Chamber of Commerce at Deming with a picture of a quadruped resembling a deer, but the base is so fractured in killing that it is difficult to determine the shape of the body or its decoration.

*Unidentified Animal.*—One of the most instructive figures of the collection appears in duplicate on a large food bowl (pl. 5, fig. 1). This vessel is black and white in color and measures fifteen inches in

<sup>1</sup> 17th Ann. Rep. Bur. Amer. Ethnol., pls. 121a, 138c. There are one or two examples of Sikyatki pottery where a geometrical design is attached to an animal figure which leads to the belief that possibly the figure attached to the rear of the above may not represent a part of another animal but rather a geometrical design of unknown significance, in this particular recalling old time Hopi ware.

diameter by six inches deep. The two designs occur on the two sides of the interior of the bowl, the middle of which is left without decoration.

The body of this creature is elongated and tapers backward, being continued into a tail like that of the lizard. The head is long and the snout pointed. Only two legs are represented, and these are situated far back on the body near the point of the origin of the tail from the body. A lozenge-shaped symbol forms the geometrical design on the side.

FIG. 27.—Unidentified animal. Oldtown Ruin. (Osborn collection.)

The presence of only two legs in this figure would seem to indicate that a bird was intended, but no bird has a tail like this figure; and the prehistoric potters of the Mimbres certainly knew how to draw a bird much better than this would imply. The exceptional features of this drawing, doubtless intentional, belong neither to flesh, fish, nor fowl, rendering its identification doubtful.

#### GRASSHOPPER<sup>1</sup>

A figure on a bowl here represented (pl. 6, fig. 1) is painted in "black or brown on a background of bluish wash over a yellow color."

<sup>1</sup>This figure may also be identified as a locust.

This bowl is eleven inches in diameter, five inches in depth. The figure is a remarkable one, having features of several animals, but none of these are more pronounced than its insectiform characters, among which may be mentioned the antennæ, three legs on one side (evidently three pairs of legs, for that in the back is simply introduced in violation of perspective), and an extended segmented abdomen attached to the thorax and terminating in a recurved tip. The character of the appendages to the thorax, or the wings, leaves no doubt that a flying animal was intended, and the legs and head being like an orthopterous insect, it may be provisionally identified as a "grasshopper."<sup>1</sup>

While the general form of head, thorax, and body appear from an inspection of the figure, it may be well to call attention to certain special features that illustrate primitive methods of drawing. The most striking of these is seen in the abnormal position of the leg which arises from the thorax on the back in the rear of the so-called wings. This abnormal position was introduced by the artist to show the existence and form of the legs on the right side; the appendage corresponds with one of the three on the left side, which have the proper position but are much smaller. A similar delineation of organs out of place not seen or turned away from the observer was common among the prehistoric artists of the Pueblo region and is paralleled by the representation of two eyes on one side of the head already mentioned. The two "wings," each ending in white circles with dots or crosses, are supposed, on the theory that this is a grasshopper, to represent wing covers or elytra, which of course the prehistoric people of the Mimbres did not differentiate from folded wings. It is possible that wing cover and wing may be represented on one side and that corresponding organs on the right side of the body are omitted. The thorax is covered with regularly arranged rows of dots formed by parallel lines crossing at an angle, forming purely arbitrary decoration representing the geometric designs on the bodies of other animals.

#### FROGS AND BIRDS

One of the few bowls obtained on which animals of two species were depicted on the same vessel was excavated by the author at Oldtown. This remarkably fine specimen (pl. 7, fig. 1) has figures of

---

<sup>1</sup> Possibly depicted on a food bowl because grasshoppers were eaten by the prehistoric people of the Mimbres.

two birds and two frogs<sup>1</sup> drawn in opposite quadrants, being unique in this particular. The two birds and frogs are not very unlike those already described but have certain characteristic features, especially in the geometric designs on their bodies.

The bowl is warped into an irregular shape and made of thin ware, probably distorted in firing. It was found under the floor of one of the central rooms in the Oldtown ruin, almost completely covering the skeleton of a baby.

On another bowl (pl. 6, fig. 2) there is depicted a frog very like that last mentioned. The frog being an amphibian was undoubtedly greatly revered by the ancient people of the Mimbres Valley.

#### HORNED SNAKE

The serpent with a horn on the head is pretty generally regarded as a supernatural being, and its pictures and effigies occur on modern Hopi, Zuñi, and other Pueblo paraphernalia. It is an ancient conception, for it is figured on prehistoric pottery from all parts of the Pueblo area, having been found as far south as Casas Grandes in Chihuahua. It is to be expected that a people like the ancient Mimbrenos who adorned their pottery with so many well drawn zoic figures would have included the horned serpent, provided this reptile was a member of their pantheon. The nearest approach to a figure of such a monster is found on a large pottery fragment found by Mr. Osborn twelve miles south of Deming. This fragment covered the cranium of a skeleton and was perforated or "killed" like a whole bowl.

A very large number of pictures of the horned snake from localities all over the Southwest might be mentioned, but a few examples are adequate to show how widespread the conception was in ancient times. They occur among the Tewa, Keres, Zuñi, Hopi and other Pueblos and vary greatly in details, but in all instances preserve the essential symbolic feature—a horn on the head and a serpentine body.

The horned serpent is known to the Hopi as the plumed serpent, and when represented by them has a bundle of hawk feathers as well as a horn attached to the head. Effigies of this being, also with horn

---

<sup>1</sup>A picture of a horned toad on a food bowl was recorded from Cook's Peak by Professor Webster, and there is a picture of what appears to be the same reptile in Mr. Osborn's collection. It is of course sometimes difficult to positively distinguish representations of frogs, toads, lizards, and Gila monsters, but the anatomical features are often well indicated.

and feathers, are used in several ceremonies, as the Winter Solstice,<sup>1</sup> and a dramatic festival<sup>2</sup> which occurs yearly in March. Wooden representations of the same horned snake are carried as insignia by a warrior society called the Kwakwantu,<sup>3</sup> in the New Fire Ceremony. The priests of the Tewan pueblo, Hano, among the Hopi also have effigies of the horned snake, the worship of which their ancestors brought to Arizona from New Mexico. These effigies are yearly made of clay and form conspicuous objects on the December altars of that pueblo.

FIG. 28.—Serpent. Osborn Ruin. (Osborn collection. E. D. O. Jr. del.)

The head shown in figure 28 has a horn curving forward almost identical with that on the head of a horned serpent on a bowl from Casas Grandes in the Heye collection. Its gracefully sinuous body is decorated with alternating geometric figures, curves and

<sup>1</sup> The Winter Solstice Ceremony. *Amer. Anthropol.*, 1st ser., vol. 11, Nos. 3, 4, pp. 65-87, 101-115.

<sup>2</sup> A Theatrical Performance at Walpi. *Proc. Washington Acad. Sci.* vol. 2, pp. 605-629. Native pictures of the Hopi horned snake may be found, pl. 26, 21st Ann. Rep. Bur. Amer. Ethnol.

<sup>3</sup> The horned serpent cult at Walpi is said to have been introduced from the south.

straight lines.<sup>1</sup> Accompanying the figure of a serpent is a well-drawn picture of a turtle which is decorated on the carapace with a rectangular area on which is painted a geometric figure recalling that on bodies of birds and some other animals.

## FISHES

One of the bowls (fig. 30) from the Oldtown ruin has two fishes depicted on opposite sides of the inner surface. These fishes resemble trout and are of different colors, black and reddish brown figures

FIG. 30.—Fish. Oldtown Ruin. Diam. 9".

painted on a white ground. They are represented as hanging from two parallel lines surrounding the rim of the bowl. These fishes are so well drawn that there is no doubt what animal was intended to be here represented. On the interior of another bowl excavated by the author at Oldtown there is a picture of a fish which recalls the two

<sup>1</sup>Of all the designs representing the horned snake known to the author this picture from the Mimbres resembles most closely the pictures of this being on pottery from Casas Grandes. It has, however, the single horn found on the clay image in the Hano altar of the Winter Solstice Ceremony, although quite unlike figures on pottery from the Pajarito region. The bodily decorations in the Mimbres bowl are unlike those of the Hopi horned snake.

just mentioned.<sup>1</sup> It may be mentioned that fishes are not represented in the beautiful specimens of pottery from Sikyatki,<sup>2</sup> possibly for the simple reason that there are no streams containing fish in the neighborhood of Hopi ruins. In the Mimbres, however, fish are still found and were no doubt formerly abundant and well known to the prehistoric inhabitants,<sup>3</sup> being looked upon by them as water symbols in much the same way as the frog is at present regarded by Zuñi and Hopi.

Another fish figured on a bowl from Oldtown, is unfortunately broken near the tail. The accompanying decoration has apparently another figure behind this fish, but its complete form is obscured by the perforation made in killing the vessel.

The most problematical of all the life figures on the Mimbres pottery is shown in plate 7, figure 2. This figure occurs on a black and white food bowl, eleven inches in diameter, four and one-half inches in depth. In support of the theory that the two figures here depicted represent fishes, we have the pointed head without neck, the operculum as a white crescentic design, two fins (pectoral, ventral, and anal), the median (adipose?) dorsal fin unpaired, and a long tail bifurcated at the extremity. The resemblance of these figures to the undoubted fishes on bowls previously mentioned is conclusive evidence that they represent the same animal.

#### GEOMETRICAL FIGURES

The geometrical designs on Mimbres pottery are rectangular, curved, and spiral, the first form being the most common. These units are arranged in twos or fours, and although they consist often of zigzag or stepped figures, the triangle and rectangle predominate. The geometrical designs are rarely colored, but commonly filled in with hachures and parallel lines. There are seldom decorations on the outside of the Mimbres bowls, in which respect they differ from ancient Hopi (Sikyatki) vessels elsewhere figured.<sup>4</sup> Conversely, that part of the interior of the bowl which surrounds the central design, oftentimes elaborately ornamented in Mimbres pottery, is very simply

<sup>1</sup> The Mimbres formerly had many more fishes than at present, and Bartlett records that his men often brought in fine trout for his camp. These, with turkeys, quail, deer and antelopes, led him to say that his "fare might be called sumptuous in some respects" (*op. cit.*, p. 236).

<sup>2</sup> Fishes are sometimes represented on Keresan pottery.

<sup>3</sup> As elsewhere mentioned in this paper, one of the bird figures (fig. 25) has a fish in its mouth.

<sup>4</sup> 17th Ann. Rep. Bur. Amer. Ethnol., Part 2, figs. 277-355.

decorated in Sikyatki pottery. Encircling lines on Mimbres pottery are continuous, whereas at Sikyatki they are broken at one or more points by intervals known as the "life gateways" or "lines of life."<sup>1</sup> The geometrical figures on the inside of every bowl sometimes surround a central region on which no figures of animals or human beings are drawn, but which is perforated.

The more strikingly characteristic forms of geometrical figures are shown in designs on plate 8. Certain of the geometrical figures drawn on the sides of animals as on the wolf (pl. 2, fig. 1), the antelope (figs. 19 and 20), the mountain sheep (pl. 2, fig. 2), the unidentified animal and bird (figs. 18 and 25), the reptile (fig. 28),

FIG. 31.—Rabbit and geometrical designs.

also appear without the animals and probably have the same significance<sup>2</sup> in both instances.

No geometrical figures were identified as representing sun, moon, earth, or rain-clouds. A few crosses, circles, triangles, and irregular quadrilateral designs combined with zigzag stepped figures and interlocked spirals and highly interesting swastikas (fig. 31) form the

<sup>1</sup> Ceremonially, every piece of pottery is supposed by the Hopi to be a living being, and when placed in the grave of the owner, it was broken or killed to let the spirit escape to join the spirit of the dead in its future home. There is no evidence that the Sikyatki mortuary pottery was purposely broken when deposited in the grave, and probably no need of perforating it to allow free exit of the spirit, for the broken encircling line, "life gateway," absent in Mimbres pottery, but almost universally present in ancient Hopi pottery, answered the same purpose, in their conception.

<sup>2</sup> Following Hopi analogies, where these geometrical figures frequently occur with animals they may have the same symbolic meaning as when alone, and represent shrines or prayer-offering houses.

majority of the designs.<sup>1</sup> Several geometric designs, as those on the bodies of figures 25 and 26, appear on Sikyatki pottery (see 17th Ann. Rep. Bur. Amer. Ethnol., plate 121); others resemble Pueblo symbols of wide distribution, but the majority are unique. The geometric designs on the bodies of life-figures vary with the animal depicted, but the same genus of animals does not always have the geometric figure, although almost identical designs occur on the bodies of different genera. It is recognized that a comparison of designs on Southwestern pottery shows a general uniformity in geometrical pattern which renders it very difficult to distinguish different local areas of development, and may be the result of more extensive inter-

FIG. 32.—Geometrical figure. (Osborn collection.)

change of ideas and a greater uniformity of cultural conditions. The pottery of the Mimbres shares with the rest of the Southwest several well-known geometrical designs which no doubt date back to an earlier epoch than the evolution of animal figures, but it also has several decorations of geometrical patterns (fig. 32) that are peculiar to it and which, taken with the characteristic zodiac figures, serve to differentiate it from other local areas. Mimbres pottery as pointed out by others has a general likeness to that from Casas Grandes Valley in Chihuahua, a resemblance which no doubt increases as we follow the river to Lakes Palomas and Guzman.<sup>2</sup> The resemblance is not close

<sup>1</sup> Unfortunately there are few decorated vases represented in the collection, but exploration in the field may later bring many of these to light.

<sup>2</sup> The author brought to Washington fragments of a food bowl from the ruin near Byron Ranch, identical with Casas Grandes ware.

enough to indicate identity, but we have enough material to support the belief that the archeological area in which it occurs is Mexican, unlike that of any other ceramic area in Arizona or New Mexico. Here a specialized symbolism has been developed which is different from that of the Rio Grande, or the Upper Gila-Salt area, and that characteristic of the great Lower Gila in which lie the compounds like Casa Grande. The Mimbres Valley archeologically is the northern extension of a culture area which reached its highest development on Casas Grandes River.

#### CONCLUSIONS

Geographically the Mimbres Valley is the northern extension of the drainage area of the large interior plateau, the lowest level of which is occupied by Palomas, Guzman, and other so-called lakes. The Casas Grandes, Mimbres, and other rivers contribute their scanty waters to these lakes, which have no outlets into the sea. As a rule the thirsty sands along the course of the river drink up the surplus waters of the Mimbres or cause them to sink beneath the surface, to reappear when the configuration of lower clay or rock formations forces them from subterranean courses. Considering the similarity in climatic and geographical conditions in the northern and southern ends of this plateau, we would expect to find cultural likenesses in the prehistoric inhabitants of the Mimbres and Casas Grandes valleys, but such is not the case. The absence of relief decoration combined with painting, so common in the pottery from the Casas Grandes region, separates the Mimbres ware from that found far to the south.<sup>1</sup>

There are evidences that the course of the Mimbres River through Antelope Plain has from time to time changed considerably, and although a section of its bed now lies east of the Florida Mountains, the river probably formerly made its way to the west of the same in its course to Mexico. Modifications or changes in the bed of this river have had in the past much to do with the shifting of population and obliteration of prehistoric sites, either by washing them away entirely or burying them out of sight or deeply below the surface. This concealment of evidences of prehistoric occupancy has also been aided by frequent sandstorms, when considerable quantities of soil have been transported from place to place and deposited on walls or covered implements lying on the surface of the ground. It is also

---

<sup>1</sup> We must look to renewed explorations to shed light on this and many other questions which the paucity of material is yet insufficient to answer.

possible that there has been a slow change of climate, causing a desiccation which may have been so widespread that the inhabitants of the plain were driven up river into the hills where water was more abundant, but it is well to remember that abandoned settlements or ruins exist on the banks of the Mimbres where there is still abundant water, as well as in the plain which is dry.

The depth of the present water level, as shown by drilling for wells, varies in different places in the valley, but in the neighborhood of the hills there are many springs. The configuration of the surface of the hard clay strata lying beneath the soil here and there often forces the water to rise to the surface, and ruins occur at points where at present there are no signs of surface water, although at the time they were inhabited there may have been more water.<sup>1</sup> Whether or not this water was brought to certain ruins by a system of artificial irrigation, the canals of which have been obliterated, we cannot say, but there is only scanty evidence that the climate here, as elsewhere, has radically changed since man occupied the valley.<sup>2</sup>

Although there is a remote likeness between the terraced house or pueblo community of northern New Mexico<sup>3</sup> and the prehistoric houses of the Lower Mimbres, its closest resemblance is to an antecedent type, for it is possible that the terraced pueblo culture in the Rio Grande Valley was preceded by another. This earlier type of habitation of the Mimbres Valley was like the fragile-walled house of the natives inhabiting a large part of Arizona and New Mexico before the Puebloan, and we have evidence that this older style of building was scattered over the present Pueblo area. There is no evidence of a terraced dwelling or pueblo more than one story high

---

<sup>1</sup> In dry seasons the river flows under the superficial soil at a varying depth, but in floods it follows the surface bed.

<sup>2</sup> As the author has pointed out in several articles, the abandonment of Southwestern ruins is due to a variety of causes, chief of which are changes of climate. It is often due to other more local causes, as attacks by hostiles, salinity of soil, poor site for defence, presence of wizards, contagious diseases, etc.

<sup>3</sup> The designation "pueblo ruins" sometimes applied to any cluster of ancient house walls in Colorado, Utah, New Mexico, and Arizona, should be restricted to a well-defined architectural type which originated and reached its highest development in a small area in New Mexico. It was eventually carried by colonists in all directions from the center of origin, becoming intrusive as far west as the Hopi, Zuñi, and Little Colorado. The boundaries of this type never extended into Mexico in prehistoric times. The ruins along the Mimbres are not community houses of terraced character and should not be called pueblo ruins.

in the Mimbres or the inland basin in which it lies. In other words the ruins of the Mimbres may be regarded as older than true pueblo ruins, resembling an earlier type of dwelling that antedated, in the Rio Grande Valley, the terraced houses.

The author does not find any architectural features in the remains of the prehistoric habitations of the Mimbres Valley suggesting Casa Grande compounds, or those massive buildings with encircling walls which are characteristic of the plains of the Gila. Although the walls of the Casas Grandes, in Chihuahua, are constructed in the same way and out of material like those of Casa Grande on the Gila, the architectural feature, an encircling wall of the latter, has not yet been recognized on the Sierra Madre plateau.<sup>1</sup> Objects found in the Gila ruins are somewhat different in form from those of Chihuahua, while pottery from the Gila Valley ruins and that from the inland plateau in northern Chihuahua is markedly different, with very divergent symbolism. Not only do forms of stone implements of a shape unknown in southern Arizona occur in southern New Mexico, but also the methods of disposal of the dead differed among the two people. The latter practised inhumation only, the other both cremation and inhumation. The aborigines of the Mimbres Valley placed a bowl over the head or face of the dead, a practice which, so far as known, does not appear to have been so commonly in vogue in inhumation of the prehistoric people of the Lower Gila plains.

The conventional geometric symbols on prehistoric Mimbres pottery are readily distinguished from those on ware from Tulerosa, a tributary of the San Francisco. The most significant feature of the Mimbres pottery is that fifty per cent of the figures on it represent men or animals, while out of a hundred bowls from the Gila not more than two or three are ornamented with zoic designs. As we know comparatively nothing of the pottery of the sources of the Upper Gila and that part of its course which lies between the Tulerosa and the Mimbres, we can at present venture very little information on ceramic relations, but similarities or mixtures would naturally be expected, due to contact or overlapping, the type of the one valley overlaying that of the other or mingling with it.

The sources of the Upper Salt, the largest tributary of the Gila, lie far from the Mimbres, and close relationship in the pottery of the

---

<sup>1</sup> This statement is made with reservation, as the true architectural form of the Casas Grandes of Chihuahua is not yet known. The published plans show no encircling wall like that of Casa Grande on the Gila: probably the Casas Grandes of Chihuahua belong to a highly specialized type different from others.

ancient people inhabiting its banks is not found or expected. It is not known whether the pottery from the Upper Salt and that from the Upper Gila is similar, for our museums have no extensive collections from the latter region from which to make comparisons and draw conclusions. We know practically nothing of the prehistoric culture of the Upper Gila.

The aborigines of the Mimbres, like those of some of the former dwellers in Pajarito Park in New Mexico, practised a modified form of urn burial, but the latter rarely decorated their pottery with figures of animals. As compared with known Pueblo ceramics, the Mimbres pottery appears to be more closely allied to ancient Keresan than to old Tewan. Judging from what remains, the houses architecturally had little in common with true pueblos.<sup>1</sup> There are no evidences of circular subterranean kivas with pilasters, ventilators, deflectors, and niches, as in northern New Mexico, although there is a fairly large proportion of subterranean rooms or pit dwellings which may have been their prototypes. Architecturally the prehistoric habitations of the Mimbres Valley represent an old house form widely distributed in the Pueblo region or that antedating the pueblo or terraced-house type before the kiva had developed.

There are not sufficient data at hand to determine satisfactorily the kinship of the prehistoric inhabitants of Mimbres Valley, but as far as may be judged by pottery symbols it may be supposed that their culture resembled that of other sedentary people of New Mexico and Arizona in early times, as well as that of peoples of Chihuahua. It appears to the author that there are so many cultural similarities among the sedentary people which inhabited the Sierra Madre plateau, of which the Antelope Plain of Mimbres Valley is only a northern extension, that we may regard their culture as closely related. A specialized high development of this inland culture took place along the Casas Grandes River, culminating in Chihuahua. The Mimbres Valley was inhabited by people somewhat less developed in culture.

Although the ancients of the Mimbres were related on the one side to the Pueblos of New Mexico and on the other to more southern people, that relationship existed between the ancestors of the same rather than with modern Pueblos, and reached back to a time before

---

<sup>1</sup> While neither the terraced nor the "compound"-type of architecture has been seen in the Mimbres for the reason that both were specialized in their distinct geographical areas, the fragile-walled, jacal type of habitation is identical in form, though not in time, in all three localities.

the terraced communal house type originated. This type of house arose in northern New Mexico and spreading from this center extended down the San Juan as far as the Hopi, while modifications are also found in certain ruins on the Gila and Little Colorado, which, like Zuñi, it profoundly influenced, but its influence never reached as far as the Lower Mimbres.

A comparison of the limited archeological material from the Mimbres with that from other localities in the Southwest suggests a provisional hypothesis that the prehistoric culture of this valley was not modified by terraced architecture nor greatly affected by that of the Lower Gila type, both of which evolved independently and locally, but belonged to an older type with which it had much in common.
